ABSTRACT

Purpose: To develop evidence-based diagnostic imaging practice guidelines to assist chiropractors and other primary care providers in decision making for the appropriate use of diagnostic imaging for spinal disorders.

Methods: A comprehensive search of the English and French language literature was conducted using a combination of subject headings and keywords. The quality of the citations was assessed using the Quality of diagnostic accuracy studies (QUADAS), the Appraisal of Guidelines Research and Evaluation (AGREE), and the Stroke Prevention and Educational Awareness Diffusion (SPREAD) evaluation tools. The Referral Guidelines for Imaging (radiation protection 118) coordinated by the European Commission served as the initial template. The first draft was sent for an external review. A Delphi panel composed of international experts on the topic of musculoskeletal disorders in chiropractic radiology, clinical sciences, and research were invited to review and propose recommendations on the indications for diagnostic imaging. The guidelines were pilot tested and peer reviewed by practicing chiropractors, and by chiropractic and medical specialists. Recommendations were graded according to the strength of the evidence.

Results: Recommendations for diagnostic imaging guidelines of adult spine disorders are provided, supported by more than 385 primary and secondary citations. The overall quality of available literature is low, however. On average, 45 Delphi panelists completed 1 of 2 rounds, reaching more than 85% agreement on all 55 recommendations. Peer review by specialists reflected high levels of agreement, perceived ease of use of guidelines, and implementation feasibility. Dissemination and implementation strategies are discussed.

Conclusions: The guidelines are intended to be used in conjunction with sound clinical judgment and experience and should be updated regularly. Future research is needed to validate their content. (J Manipulative Physiol Ther 2008;31:33-88)

Key Indexing Terms: Practice Guideline; Guideline; Diagnostic Imaging; Radiology; Diagnostic X-Ray; Radiography; Adult; Musculoskeletal System; Pain; Cervical Spine; Thoracic Spine; Lumbar Spine; Trauma

Reporting of Topics Included in the Development of the Diagnostic Imaging Practice Guidelines

An initial literature review considered 10 clinical questions pertaining to imaging of musculoskeletal conditions to evaluate the pertinence of developing diagnostic imaging guidelines. This initial review led to a research project divided into 9 phases: (1) literature search; (2) independent literature assessment; (3) guideline development specific recommendations; (4) first external review; (5) consensus panel (modified Delphi); (6) public website; (7) second external review; (8) final draft and grading of the recommendations; and (9) dissemination and implementation. Details of this study are published elsewhere.

Focus

These diagnostic imaging guidelines concern adult musculoskeletal disorders of the spine where conventional radiography and specialized imaging studies are deemed useful for diagnostic purposes. Special consideration for manual therapy intervention is integrated within these guidelines.

Objectives

Reasons for developing these guidelines include assisting current and future health care providers to make appropriate use of imaging studies, providing indications for the need of
imaging studies according to current literature, and expert consensus, and assisting in optimizing the utilization of limited available resources. These proposed guidelines are intended to reduce unnecessary radiation exposure and the use of specialized imaging studies, increase examination precision and decrease health care costs—all without compromising quality of care.

Target Users/Setting

Intended users of the guidelines are chiropractors and other primary health care providers prescribing diagnostic imaging studies. The setting in which these guidelines may be used include private clinics, outpatient clinics, and hospital emergency rooms.

Target Population

The patient population eligible for guideline recommendations are adult patients presenting with musculoskeletal disorders of the spine. Children and pregnant patients are excluded from these guideline recommendations.

Developers

The proposed guidelines are developed from the results of 9 distinct phases overseen by a research team composed of the 3 investigators with postgraduate education from 3 independent teaching institutions. The guidelines were further developed and peer reviewed by more than 60 chiropractic clinicians, academics, and researchers.

Evidence Collection

Electronic searches in English and French language literature occurred and cross references were repeated on 3 different occasions between 2003 and 2006.

METHODS FOR SYNTHESIZING EVIDENCE

(a) Literature search and independent literature assessment of spinal disorders: Quality of diagnostic accuracy studies (QUADAS),\(^5\) Appraisal of Guidelines Research and Evaluation (AGREE),\(^4\) and Stroke Prevention and Educational Awareness Diffusion (SPREAD).\(^5\)

(b) Initial draft: template based on European Commission classification (2001).\(^6\)

(c) Expert consensus: a 2-round modified Delphi process was used to generate consensus among an international panel of more than 60 experts in musculoskeletal disorders.

Recommendation Grading Criteria

The evaluation tool used was designed by the Scottish Intercollegiate Guidelines Network (SIGN) and adapted by the Stroke Prevention and Educational Awareness Diffusion (SPREAD) group.\(^5,7\)

Patient Preferences

Condition specific imaging guidelines. Integral to evidence-based health care, decisions regarding the use of imaging studies should be based on the best available evidence, the experience, and judgment of the clinician, while considering the patient preference. A public member reviewed all documents and provided comments and suggestions.

Stakeholders and Editorial Independence

(a) Prerelease review: Before the release of the guidelines, the reliability of proposed recommendations was tested on specialists both in chiropractic and in medicine as well as on practicing chiropractors.

(b) Potential conflict of interest: The research team involved in the development of these guidelines declare no existing or potential conflict of interest. No investigators have received or will receive any personal financial benefits or derive any salary from this project.

(c) Funding sources/sponsors:

1. Canadian Memorial Chiropractic College Post Graduate Education and Research (2005)

Updating/Revision

The literature review and the guidelines should be updated every 2 to 3 years.

Potential Benefits and Harm

Selection of appropriate radiologic imaging procedures for evaluation of patients with musculoskeletal disorders of the spine; decrease unnecessary ionizing radiation exposure, decrease costs, and improve accessibility.

Dissemination/Implementation Considerations

Publication; applying to National Guideline Clearinghouse; posting of the electronic document on various websites (malpractice insurance carriers, outpatient teaching clinics); educational intervention strategies (e-learning, community pilot studies); referral guidelines; reinforced by request checking and clinical management algorithms; promotion by national, provincial and state organizations, conferences.

Definitions, Patient Presentations, Recommendations, and Rationale

These topics are integral parts of each of the 3 diagnostic imaging guidelines: lower extremity disorders, upper extremity disorders, and spine disorders. Results of the 9 phases of the research project are published elsewhere.\(^2\)

PRELIMINARY CONSIDERATIONS AND DISCLAIMER

What Is the Role of These Guidelines?

These evidence-based diagnostic imaging practice guidelines are intended to assist primary care providers and students in decision making regarding the appropriate use of diagnostic imaging for specific clinical presentations. The guidelines are intended to be used in conjunction with sound clinical judgment and experience. For example, other special circumstances for radiographic imaging studies may include: patient unable to give a reliable history; crippling cancer phobia focused on back pain; need for immediate decision
about career or athletic future or legal evaluation; history of significant radiographic abnormalities elsewhere reported to patient but no films or reliable report reasonably available; history of finding from other study (eg, NM or gastrointestinal imaging) that requires spine radiographs for correlation. Application of these guidelines should help avoid unnecessary radiographs, increase examination precision, and decrease health care costs without compromising the quality of care.

The descriptions of clinical presentations and proposed clinical diagnostic criteria, recommendations for imaging studies, and the comments provided throughout this document are a synthesis of the vast body of literature consulted before and during the various phases of this research project.

Where the literature was found to be of poor quality or absent, consensus based on expert opinion was used. Although the investigators and collaborators carefully searched for all relevant articles, it is probable that some have been missed. Furthermore, as many new important studies are published in the near future, these will be incorporated in subsequent revisions of the guidelines and recommendations may change accordingly.

What These Guidelines Do and What They Do Not Do

It should be emphasized that these guidelines were developed with the intent of being used for diagnostic purposes and not for therapeutic purposes such as evaluating and monitoring functional or structural rehabilitation of the spine. In addition, these guidelines are intended to address issues faced by first contact professionals only. These guidelines do not address all possible conditions associated with musculoskeletal disorders, only those that account for the majority of initial visits to a practitioner.

Like other diagnostic tests, imaging studies should only be considered if (a) they yield clinically important information beyond that obtained from the history and physical examination; (b) this information can potentially alter patient management and; (c) this altered management has a reasonable probability to improve patient outcomes.

Investigators and collaborators in the development of these imaging guidelines believe that liability insurance companies, third-party payers, and courts of law should not rely solely on descriptions of patient presentations, proposed recommendations, and/or corresponding comments found throughout the documents, as patient presentations are unique and the application of any guideline always requires clinical judgment and thus needs to be considered in the proper context. In addition, laws and regulations may vary between geographical regions and should be considered when applying the proposed indications for any imaging study.

What Is Evidence-Based Health Care?

Evidence based is about tools, not about rules. Evidence-based health care is an approach in which clinicians and health care professionals use the current best evidence in making decisions about the care of patients. It involves continuously and systematically searching, appraising, and incorporating contemporaneous research findings into clinical practice. The overall goal is improving patient care through life-long learning.

Potential Disagreements

There are several reasons for disagreement within a guideline development group. These include differences in interpretation of the research literature, differences in personal experience, and different perceptions of the inherent risks and benefits of a procedure. Divergent or competing guidelines on similar topics serve only to further confuse and frustrate practitioners. In addition, the continued lack of unity among chiropractors hinders its growth by limiting integration and cooperation within the greater health care system. Readers of all guidelines are advised to critically evaluate the methods used as well as the content of the recommendations before adopting them for use in practice.

Standard Patient Management Activities

Standard patient management activities, including diagnostic assessment and follow-up, are integral components of every patient encounter. Initial triage of patients with spine disorders is a constant recommendation of various clinical guidelines. Imaging studies are used most practically as confirmation studies once a working diagnosis is determined. The objective is to determine the presence of clinical indicators of serious pathologies (red flags) requiring diagnostic imaging, specialist referral or urgent surgical intervention. When a practitioner recommends that a radiograph or other diagnostic imaging study be performed, and the patient refuses, the patient should be advised of the associated risks and implications and this should be recorded in the patient’s records.

Duration of Disorders

In clinical practice, spine disorders are generally divided into categories according to the duration of the patient complaint on initial presentation. These diagnostic imaging guidelines therefore consider the following categories of clinical presentations: acute spine disorder (<4 weeks’ duration); subacute spine disorder (4-12 weeks’ duration); and persistent/chronic spine disorder (>12 weeks’ duration).

Defining Radicular Pain

It is generally accepted that patients with neurologic symptoms and signs (pain radiating below the knee or beyond the elbow, as intense as the low back or neck pain, often radiating into the foot or hand with numbness or paresthesia in a dermatomal distribution with positive nerve root tension signs, abnormal motor power, sensation or deep tendon reflexes consistent with a nerve root involvement) have a slower resolution than patients with uncomplicated spine disorders (mechanical pain that varies with time and activity with no neurologic component and a good general health status). Again, clinical presentations are divided accordingly throughout these imaging guidelines.
Table 1. Thoracolumbar, lumbar, and thoracic spine trauma

<table>
<thead>
<tr>
<th>Patient presentation</th>
<th>Recommendations</th>
<th>Comments</th>
</tr>
</thead>
</table>
| Adult patient with recent (<2 wk) acute thoracolumbar, lumbar or thoracic spine trauma. | Radiographs not routinely indicated [C] | In a recent survey, 53% of patients consulting chiropractors reported having an injury. The most common reported source was non–work related (43%); work-related injuries accounted for only 16%, and 21% were classified as nonspecific. Physical examination is reliable in this region. When the patient is alert and asymptomatic, injury risk is low and radiographs provide no clinical utility.

Absence of pain, normal ROM, and absence of neurologic deficits (normal lower limb motor power, sensation and deep tendon reflexes, and no pathologic reflexes).6 | | Increased prevalence of traumatic fractures found in patients >75 yoa. Prevalence of lumbar spine traumatic fracture is <1% but overall prevalence of spine fractures for all age groups is 4% [43,44].

Adult patient with thoracolumbar, lumbar, or thoracic spine blunt trauma or acute injuries (falls, motor vehicle accidents [MVAs], motorcycle, pedestrian, cyclists, etc) High-risk screening criteria for spinal injuries include any of the following45-49: 1. Back pain 2. Midline tenderness on palpation 3. Distracting painful injury and other high-risk mechanism of injury* 4. Neurologic deficits** 5. Altered consciousness (caused by head trauma, intoxication/ethanol, or drugs) Sensitivity of 100% (95% CI, 98%-100%) but low specificity and low positive predictive value for thoracolumbar injuries. | Radiographs indicated [B] Lumbar AND thoracic spine: AP (or PA), lateral views N.B. The high-risk screening criteria for spinal injuries was developed to help determine the need for plain film radiography in the emergency room. The lower prevalence of serious post traumatic injuries in ambulatory care likely influence the sensitivity of such instruments. Nonetheless, it appears reasonable to recommend their use in primary care as well as well. | Conventional radiography is highly specific but has a sensitivity of ≥0.70 and a predictive value of 0.92 [45-46]. Thoracic and lumbar spinal injuries affect 2%-3% of blunt trauma victims with a 40%-50% incidence of neurologic deficits.7 Major spine traumas are typically seen in hospital settings and mandate immobilization pending radiographic evaluation. Missed spinal injuries resulting in neurologic deficit continue to occur in major trauma centers. Older age (>50), high impact accidents, patients with insufficient imaging, and misread or poor quality radiographs are at highest risk of missed injuries.80 The Thoracolumbar Injury Severity Scale (TLISS) may be helpful in the referral decision making process. The scale is based on the mechanism of injury, the integrity of the posterior ligamentous complex, and the neurologic status.51-53 (See Appendix C(1) for details)

* High-risk mechanism of injury: Severe mechanism of injury (falls ≥10 ft/3 m, ejection from a motor vehicle, and motor vehicle crashes >50 mph/80 km) and the presence of cervical spine fracture are significantly associated with an increase risk of thoracolumbar spine injury.

** Neurologic deficits: a. Lumbar spine injuries: positive nerve root tension signs decreased motor power, sensation, and/or deep tendon reflexes. b. Thoracolumbar and thoracic spine injuries: lower limb spasticity, presence of pathologic reflexes (Babinski sign/clonus), altered sensations below the injury (sensory level), and altered proprioception (vibration/position sense of the feet), loss of anal sphincter tone.

• Patient with spinal injuries may suffer progressive neurologic deterioration, and imaging again has a role in their diagnosis and management.9

For osteoporotic fracture risk, please see Pain—Osteoporotic Vertebral Collapse section of the Adult Thoracic Disorders Guideline. | Special investigations [C] | Advanced imaging and specialist referral recommended: a. In presence of a fracture as suggested by history, examination, and/or radiograph. Special attention required in presence of complex lesions and for suspected ligamentous instability or neural injuries; b. If conventional radiographs are difficult to interpret; c. In the absence of clinical improvement after 4-6 wk of therapy; d. Function does not improve or deteriorates; e. Patient has persistent S&S.

• CT scan (multidetector/multislice CT and spiral CT) highly sensitive (99.3%-100%); specificity of 97%; negative predictive value of 92% [45,54,55].
• MRI provides the best evaluation for soft tissue pathology, intrinsic or compressive spinal cord damage and multilevel vertebral fractures. MRI needed when conventional radiographs and CT do not explain patient’s symptoms, and when there is a possibility of epidural hematoma or traumatic disc herniation [45].

### Table 2. Cervical spine trauma

<table>
<thead>
<tr>
<th>Patient presentation</th>
<th>Recommendations</th>
<th>Comments</th>
</tr>
</thead>
</table>
| Adult patient with acute neck injury and negative CCSR (Canadian Cervical Spine Rule for Radiography in Alert and Stable Trauma Patients) | Radiographs not routinely indicated [B] | Whiplash incidence is between 70 and 360 cases per 100000. Traumatic unstable injuries are rare (<3%). The CCSR is superior to physician judgment, more sensitive and specific than the National Emergency X-Radiography Utilization Study criteria/NEXUS.

Conventional radiographs are unlikely to show clinically significant injuries when all Canadian Cervical Spine Rule criteria are fulfilled.

(A) Any high-risk factors in alert and stable patient?
1. Age >65 (see NEXUS in comment section)
2. Dangerous mechanisms of injury*
3. Paresthesia in extremities

(B) Any low-risk factors that allow ROM assessment?
1. Simple rear end collision**
2. Patient seated in the waiting room
3. Ambulatory at one time since trauma
4. Delayed cervical pain onset
5. Absence of midline cervical tenderness

(C) ROM assessment: Is patient able to actively turn his/her head to 45° in both directions?

* Dangerous injury mechanism:
  - Fall >3 ft/5 stairs
  - Axial cranial force (such as diving)
  - Road accident >100 km/h, ejected from vehicle or rollover
  - Motorized recreational vehicle (ATV, snowmobile, etc)

** Rear end collision excludes:
  - Being pushed into oncoming traffic
  - Hit by a bus or large truck
  - Rollover
  - Hit by high speed vehicle (≥100 km/h)

Sensitivity 100% (95% CI, 98%-100%) and specificity 42.5% (95% CI, 40%-44%).

Although patients >65 years are more prone to cervical spine fractures, data form NEXUS indicates that being >65 is not, by itself, a risk factor if all criteria are considered. (Sensitivity 100% (95% CI.) Cervical spine radiographs are not indicated if patients fulfill all 5 NEXUS low-risk criteria for head and/or cervical spine trauma:

(1) Normal level of consciousness (may be temporarily confused, have mild dizziness or headache)
(2) No evidence of intoxication
(3) Absence of tenderness on palpation of the midline of the neck
(4) Absence of focal neurologic deficit
(5) Absence of painful traction injury

Rare injuries may be missed, when the CCSR or NEXUS is properly applied, findings are generally considered not clinically significant; spinous or transverse process fracture, <25% single anterior compression fracture, isolated avulsion injury not associated with ligamentous injury, type I odontoid fracture, end plate fracture, osteophyte fracture excluding teardrop or corner fracture, trabecular bone injury.

NB. “Not clinically significant missed injuries” may be relevant to manual therapy practitioners. However, considering soft tissue and bone healing time; recommendations include early activation and a gradual progression from mobilization to SMT. SMT recommended only when patient can tolerate pre-SMT position test.

Of interest, the hypothesis that early aggressive conservative care promotes faster recovery was not supported in a recent population-based cohort study.

<td>Low back pain on initial presentation is typically classified according to the duration of complaint and type of presentation: uncomplicated/nonspecific LBP, associated with neurologic deficits or to some underlying pathology. Duration of complaint: Acute LBP: &lt;4 wk of duration Subacute LBP: 4-12 wks' duration Persistent/chronic LBP: &gt;12 wks' duration</td>
<td>The cumulative 6-mo incidence of LBP is 18.6% (95% CI, 14.2-23.0) with 17.2% having mild pain (95% CI, 12.9-21.5), 1.0% having intense pain (95% CI, 0.0-2.2), and 0.4% disabling pain (95% CI, 0.0-1.0). Annual course of back pain is as follows: • 27.3 of low back complaints resolve • 29% improve • 35.4% persist • 9.3 get worse • 31.3% recur</td>
</tr>
<tr>
<td>Adult patient with acute uncomplicated* LBP (&lt;4 wks' duration) * Uncomplicated definition: nontraumatic LBP without neurologic deficits or indicators of potentially serious pathologies)—(see red flag list for details).</td>
<td>Radiographs not initially indicated</td>
<td>Routine use of lumbar spine conventional radiography is not indicated because of very low incidence of unexpected findings on radiographs (only 1 in 2500 radiographs), high radiation dose to gonads, high cost/benefit ratio, and poor association between patient findings and LBP (ie, not specific). Anomalies of no proven clinical relevance include block vertebrae, spina bifida occulta, mild scoliosis, and facet tropism; none of which are considered contraindications to SMT.</td>
</tr>
</tbody>
</table>

Mechanical LBP accounts for the vast majority of LBP seen in primary care setting. Mechanical designates anatomical or functional abnormality without an underlying pathology. For most young or middle-aged adults, early diagnostic evaluation of low back complaints may focus on 3 basic questions: diagnostic imaging is infrequently required. 1. Is there underlying systemic disease? Special investigations not indicated [B] Several factors influence the reliability and validity of biomechanical and postural analyses on conventional radiographs: Morphologic asymmetries, geometric and positional distortions, measurement errors, poor correlation with symptoms and lack of convincing clinical usefulness. Acute LBP is generally due to musculoskeletal conditions that respond favorably to SMT. A multidisciplinary panel recommended 2 trial courses of 2 wk each, using

<tbody>
<tr>
<td>2. Is there neurologic impairment that might require surgical intervention?</td>
<td></td>
<td>Alternative manipulative procedures. (^{148,149}) Lumbar spine radiography recommended in the absence of expected treatment response or worsening after 4-6 wk.</td>
</tr>
<tr>
<td>3. Is social or psychological distress amplifying or prolonging the pain?</td>
<td></td>
<td>Serious adverse events are unlikely to occur with chiropractic treatment for LBP. (^{115}) Contraindication for lumbar SMT includes progressive neurologic deficits, S&amp;S of cauda equina syndrome, suspicion of abdominal aortic aneurysms or destructive and bone softening diseases such as Paget’s disease, and severe osteoporosis. (See LBP with red flag’s for details).</td>
</tr>
<tr>
<td>There is strong evidence that in nonspecific LBP, conventional radiography and MRI findings do not correlate with clinical symptoms or work capacity. (^{103,104}) In the absence of red flags as revealed by the history and physical exam, radiography in patients with LBP of at least 6 wk duration is not associated with improved physical functioning, severity of pain, disability, or overall health status. Conventional radiography may somewhat improve patient satisfaction. However, minor psychological improvement should be balanced against radiation dose, higher number of doctor visits, and increased disability at 3 mo. (^{103-108})</td>
<td>Radiographs not initially indicated [B]</td>
<td></td>
</tr>
<tr>
<td>Adult patient with uncomplicated subacute (4-12 wks’ duration) or persistent LBP (&gt;12 wks’ duration) AND no previous treatment trial(^ {63,101})</td>
<td></td>
<td>As with all cases, recent previous available radiographs should be reviewed by the clinician. Overall, studies have not shown any significant correlation between posture and LBP. Degenerative processes (disc &amp; facet) are common &amp; usually related to age (prevalence &gt;62% in patients &gt;55 yoa). Degenerative processes may account for 10% of all LBP. Abdominal aortic calcification may be associated with lumbar disc degeneration, back pain. However, even if DJD and DDD are present, clinical management remains essentially unchanged. (^{52-53,113,121,156-156})</td>
</tr>
<tr>
<td>Consider a clinical evaluation of risk factors for chronic LBP (yellow flags). Look for functional disability, significant depression, and risk profile for delayed recovery. A trial of 4-6 wk of conservative care is appropriate before radiographs.</td>
<td>Radiographs not initially indicated [B]</td>
<td></td>
</tr>
<tr>
<td>Adult patient with nontraumatic acute LBP (&lt;4 wks’ duration) AND sciatica (no red flags)(^ {63,101})</td>
<td></td>
<td>The natural course of acute sciatica caused by lumbar disc herniation (LDH) is benign as most patients improve during the first 4 wk, (^ {157}) whereas 5%-25% are recurrent or persistent. (^ {158,159})</td>
</tr>
<tr>
<td>The first clinical clue to neurologic impairment usually is a history of sciatica: sharp pain radiating down the posterior or lateral aspect of the leg, often associated with numbness or paresthesia.</td>
<td>Radiographs not initially indicated [B]</td>
<td>Patient S&amp;S should not increase while in the premanipulative side posture, in which case SMT should not be attempted. Treatment approach should be adapted to further reduce complication risks. (^{150,151}) Ongoing clinical assessment is necessary each visit to detect any early signs of CES. (^{162,163}) — (see red flags for details).</td>
</tr>
<tr>
<td>Specific clinical diagnoses:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Common causes of sciatica</td>
<td>Radiographs not initially indicated [B]</td>
<td>The natural course of acute sciatica caused by LDH is favorable. (^ {157}) A trial of conservative care may first be attempted. (^ {171,172}) SMT appears to be a safe &amp; effective treatment for nonprogressive S&amp;S of lumbar disc protrusion, especially when compared to common treatments for LDH, such as NSAIDs and surgery. (^ {100,101,172,180}) It is estimated only 2% of all patients who have LBP will undergo surgery for disc herniation, representing 5%-10% of all cases of LDH. (^ {166,176})</td>
</tr>
<tr>
<td>Historical and physical findings are the key factors in assessing neurologic compromise. (^ {99}) (\text{(A) Suspected LDH}^{44,163-170}), • Symptomatic LDH represents 4%-5% of causes of LBP. • Risk factors for LDH include: men (1.6 times more likely), middle-aged (35-54 yoa), repetitive heavy lifting, current smoking, obesity (high BMI), and type of occupation. • Predominantly leg pain, typically involving the foot. • &gt;95% of clinically important LDH involve the L5 or S1 nerve root. • Straight leg raise is sensitive (0.8) but nonspecific (0.5); Special investigations not initially indicated [C]</td>
<td>MRI within the first 4-6 wk of suspected LDH is necessary only if there is progressive neurologic deficit or intolerable pain levels despite conservative care and surgical referral is planned. (^ {99}) Disc abnormalities may be classified on MRI according to the following:</td>

<tbody>
<tr>
<td>• Crossed SLR is highly specific (0.8) but not sensitive (0.3)</td>
<td>Radiographs indicated if patient age &gt;50 or has progressive neurologic deficits: PA (or AP), lateral lumbar views [GPP]</td>
<td>Modic classification: 4A—herniated disc protrusion with an intact annulus; 4B—extrusion with rupture of either the annulus or the posterior longitudinal ligament, or both (extrusion appears to be rare in asymptomatic adults); 4C—rupture of the annulus and the posterior longitudinal ligament with sequestration of a disc fragment in the spinal canal.</td>
</tr>
<tr>
<td>• Look for lower limb sensory, motor, and reflex deficits</td>
<td>See Appendix C(3) for a detailed list of clinical criteria for LDH.</td>
<td></td>
</tr>
</tbody>
</table>

### (B) Suspected degenerative spondylolisthesis/lateral stenosis
- Back pain with or without leg pain
- Increase pain with activity
- S&S with or without neurologic deficit

**Radiographs indicated** if patient age >50 or has progressive neurologic deficits: PA (or AP), lateral lumbar views [GPP]

**Special investigations not initially indicated** [C]

If clinical signs suggest instability: please see special investigations in: Re-evaluation of LBP for critical exclusionary diagnoses.

- A trial of conservative care may first be attempted

### (C) Suspected lumbar degenerative spinal stenosis
(3% of all LBP)
- MC >65 yoa (sensitivity of 0.7; specificity of 0.69)
- Neurogenic claudication: severity of back and leg pain commonly increase with ambulation/standing/walking downhill and improve while seated (flexed spine). Absence of pain when seated, rather than improved pain, has low sensitivity (0.46) but is very specific (0.93);
- Variable neurologic deficit (numbness, weakness)

**Radiographs indicated** if patient age >50 or has progressive neurologic deficits: PA (or AP), lateral lumbar views [C]

**Special investigations not initially indicated** [C]

Conventional radiography is of limited value in assessing spinal stenosis. As many as 20% of asymptomatic adults >60 yoa have imaging evidence of spinal stenosis and the prevalence of symptomatic stenosis is unknown. Spinal stenosis may be caused by bone (facet hypertrophy, osteophytes, etc), soft tissue (bulging disc or thickened ligamenta flava, etc), or both.

- A trial of conservative care may be attempted first.

### Suspected causes of sciatica:

(A) Lumbar disc herniation
(B) Degenerative spondylolisthesis/lateral stenosis
(C) Lumbar degenerative spinal stenosis

Results from specialized imaging should always be interpreted in light of the clinical findings. Inappropriate utilization of these highly sensitive examinations will produce false-positive results which may result in labeling of patients and contributing to an unfavorable prognosis.

**Special investigations not initially indicated** [C]

Comanagement or specialist referral recommended even if conventional radiographs are unremarkable:
1. After failed conservative therapy (4-6 wk)
2. For preoperative planning;
3. If neurologic status is deteriorating (progressive deficit, disabling leg pain); New disc extrusion and nerve root impingement may be the most important findings on MRI.

- Substituting rapid MRI for radiographic evaluations in the primary care setting may offer little additional benefit to patients, and it may increase the cost of care because of the increased number of spine surgeries that patients are likely to undergo.

- MRI sensitivity (0.6-1.0) & specificity (0.72-0.99) for LDH is slightly higher than those for CT (0.62-0.9 & 0.7-0.87) but very similar for the diagnosis of spinal stenosis (0.9 & 0.72-0.99).

### Adult patient re-evaluation in the absence of expected treatment response or worsening after 4 to 6 wk

Should patient fail to improve as expected or marginally improve within 4-6 wk of initial evaluation, the clinician must review history and physical findings and request appropriate diagnostic imaging studies.

**Radiographs indicated** [B] PA (or AP), lateral lumbar views

**Additional views not routinely indicated** [C]

- a. Lateral lumbosacral spot
- a. If poor visualization of lumbosacral junction on lateral view

<tbody>
<tr>
<td>Adaptation of the plan of management partly relies on the ability to predict patient disability status or long-term return to work status. Patient perception of the likelihood of returning to his/her usual activities should be measured after 4 wk of disability or at the time of first consultation if the patient has a history of persistent spinal pain with prolonged disability. Validated questionnaires are available to help clinicians.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b. Oblique c. Lateral flexion films may be indicated in scoliosis evaluation

b. Rarely adds clinical information & doubles radiation exposure to patient. Sometimes used to confirm presence of spondylolysis suspected from the AP & lateral films (also for suggestion of malignancy, fracture, etc.).

c. Low reliability of lateral flexion film for biomechanical assessment. Lateral bending films useful for scoliosis evaluation (see Scoliosis section).

Special investigations [C]

Comanagement or specialist referral recommended even if conventional radiographs are unremarkable AND anyone of the following:

1. In presence of a potentially serious pathology as suggested by the patient history, examination and/or radiograph;
2. After failed conservative therapy (4-6 wk);
3. If patient neurologic status is deteriorating (progressive deficit, disabling leg pain);
4. If clinical signs suggest instability. Presumed instability is loosely defined as >10° of angulation or 4 mm of vertebral translation on flexion and extension lateral radiographs. However, diagnostic criteria, natural history, and surgical indications remain controversial.
5. For preoperative planning;

While MRI is excellent for identifying tumor, infection, and nerve compression, it can be overly sensitive with regard to degenerative disease findings and frequently displays pathology that is not responsible for the patient's symptoms. See Carragee and Hannibal (2004) and Saal (2002) for a review of diagnostic testing in chronic LBP.

**Risks of having a serious pathology may be higher before the age of 20 or over the age of 55. Particular attention to indicators of possible underlying pathology should be given for patients in these age categories.**

Radiographs indicated [B] PA (or AP), lateral lumbar views. Main purpose of lumbar spine radiographs is to exclude LBP caused by: malignancies (sensitivity of 0.6, specificity of 0.95-0.99); infective spondylitis (sensitivity of 0.82, specificity of 0.57); inflammatory SpA (low sensitivity for AS [0.25-0.45], but highly specific), fractures; and instability (sensitivity of 0.51-0.99, specificity of 0.68-0.99). High false-positive and false-negative rates are reported when assessing segmental instability by radiography.

The major diagnostic task is to distinguish the vast majority of uncomplicated LBP from the 5% with serious underlying diseases or neurologic impairments.

Probability of encountering disease requiring specialized therapy in patients with LBP using radiographs is <0.2 in 100 and the probability of tumors or infection would be <1 in 1000. Normal radiographs may falsely reassure clinicians as important causes of LBP are not easily identified with conventional radiographs (ie, not sufficiently sensitive).

<tbody>
<tr>
<td><strong>Suspected inflammatory—spondyloarthropathies (SpA)</strong> (0.3% of all LBP): chronic LBP and asymmetric peripheral arthritis, predominantly of the lower limbs, are the leading symptoms for SpA.</td>
<td><strong>Additional views [C]</strong></td>
<td>Additional views may be considered in the presence of inflammatory spondyloarthropathy symptoms, although SI joints usually adequately demonstrated on AP lumbar spine.</td>
</tr>
<tr>
<td>Features of inflammatory back pain include significant morning stiffness (&gt;1 h); pain duration ≥3 mo; persisting motion restriction; gradual onset ≤age 40; peripheral joint involvement; UTI, urethral discharge. iritis. skin rash. SI stress tests poorly reproducible. AS is regarded as the most severe subgroup. A new set of criteria for inflammatory back pain of all</td>
<td>Spot AP or PA angled lumbosacral, oblique SI views</td>
<td>The modified New York criteria for AS diagnosis require the presence of radiographic sacroiliitis to classify the patient as having AS. However, plain radiographic abnormalities of the SI joints are a relatively late feature of disease. New approaches for an earlier diagnosis of axial and peripheral SpA have been proposed recently. A combination of clinical, laboratory, and imaging parameters is usually necessary.</td>
</tr>
<tr>
<td><strong>Suspected neoplasmia (0.7% of all LBP):</strong> Considerable LBP starting ≥age 50, Hx of cancer/carcinoma in the last 15 y (likelihood ratio of &gt;15), unexplained weight loss (&gt;4.5 kg over 6 mo), failure of conservative care (4 wk). A combination of the above 4 features has a 100% sensitivity for cancer. Other features include no relief with bed rest (sensitivity of 0.90, but low specificity); ESR &gt;50, nPh, scintiscan, systemically unwell; lymphadenopathy; dermopathy (melanoma).</td>
<td><strong>Additional views in complicated LBP [B]</strong></td>
<td>Advanced imaging and specialist referral recommended even if conventional radiographs are unremarkable:</td>
</tr>
<tr>
<td><strong>Suspected compression fracture (3-4% of all LBP):</strong> Recent significant trauma (any age), Hx of repetitive stress of sufficient severity; Hx of high-risk osteoporosis: Severe onset of pain with minor trauma in patients ≥age 50 (higher risk ≥age 70 with a likelihood ratio of 5.5), Hx of prolonged corticosteroids intake (&gt;7.5 mg/d &gt;3 mo) has a likelihood ratio of 12; structural deformity—a complaint of LBP in persons at risk may require both thoracic and lumbar radiographs.</td>
<td>Even if conventional radiographs are negative:</td>
<td>1. In the presence of a potentially serious pathology as suggested by the patient history, examination, and/or radiograph; 2. In the absence of clinical improvement after 4-6 wk of therapy; 3. If function does not improve or deteriorates; 4. If patient neurologic status is deteriorating (progressive deficit, disabling leg pain); 5. With painful or progressive structural deformity; 6. For unstable segment (spondylolisthesis or pathological process); 7. When patient has persisting S&amp;S; 8. In complication from treatment (possible fracture, new/progressive neurologic deficit, considerable pain, or disability, etc)</td>
</tr>
<tr>
<td><strong>Suspected infection (0.01% of all LBP):</strong> age &gt;50, documented fever (&gt;38.3°C/101°F) for &gt;3 wk</td>
<td>a. MRI is generally the preferred investigation. b. CT may be needed for bony details. (especially multiplanar reformatted images)</td>
<td>MRI or CT useful in the detection of bone and soft tissue structures. The choice of study depends on the current clinical question, availability of equipment, and costs.</td>
</tr>
</tbody>
</table>

**Special investigations in complicated LBP [B]**

- Even if conventional radiographs are negative:
  - a. MRI is generally the preferred investigation.
  - b. CT may be needed for bony details. (especially multiplanar reformatted images)

**Suspected cancer:** MRI is especially useful for marrow-based lesions. Sensitivity is highest for MRI (0.83-0.93) and radionuclide scanning (0.75-0.98); specificity was highest for MRI (0.9-0.97) and radiography (0.95-0.99).

**Suspected infection:** MRI is more accurate than radiography and bone scan (sensitivity of 0.96 & specificity of 0.92) for suspected osteomyelitis, spondylodiscitis, septic disc, paraspinal abscess, epidual abscess.

**Suspected acute inflammation in sacroiliac joints and spine:** Contrast-enhanced MRI is both sensitive & specific for active sacroiliitis (0.99 & >0.95). Although more sensitive.
The most consistent finding of a CES is urinary incontinence before age 50. AAA prevalence increases with age (3% in <65 yo & >8% in >65). About 25% mimic musculoskeletal LBP pain and 75% may be silent (incidental findings on physical examination and/or radiography) until rupture or size draws attention.

<td>Abnormal laboratory examination: R/O marrow-based malignancies, including metastasis &amp; primary marrow-based pathology (e.g. myeloma); serum gammopathy and possible infection &amp; arthritis</td>
</tr>
<tr>
<td>Abnormal laboratory examination and positive S&amp;S: ESR &gt;50 mm/h; Rh factor; HLAB27; reduced hematocrit; elevated white blood count; ALP; PSA; serum calcium for example.*211,212</td>
<td></td>
<td>It is vital to recognize the S&amp;S of CES as this is a surgical emergency. Although several etiologies can cause CES (spinal tumors, epidural abcess, etc), it usually arises from a massive midline posterior disc hemiation (represents 1%-2% of all operated LDH). Narrowing of the spinal canal (congenital or degenerative stenosis) is a likely predisposition to CES. To facilitate the early detection of rare but serious complications associated with disc hemiations, inquiry should also be made regularly during visits with regard to saddle anesthesia or any changes in bladder or bowel functions which may suggest the development of cauda equina syndrome. The risk of SMT causing a clinically worsened disc hemiation or CES in a patient presenting with an LDH has been estimated to be &lt;1 in 3.7 million manipulations, but others have proposed figures as low as 1 in 100 million SMT. The association in some reported cases has been described as temporal rather than causal.*34,149,161,182,220,223</td>
</tr>
</tbody>
</table>

### Referral or special investigations [B]

- In nondissecting AAAs, medical referral and specialized imaging recommended [B]
- If clinical findings are equivocal, medical referral and specialized imaging recommended [B]

### Special investigations [C]

- See previous page for details

### Recommendation for AAAs (symptomatic or not): Rate of growth of small AAAs is relatively predictable. The sensitivity of ultrasound (US) scanning for AAA is 95%, and the specificity approaches 100%; the examination is safe and reliable.*233

### Management*42,226,227,228-233,236-240

- Ultrasound screening: Recommended in males 65 to 75 yo (up to 80 in some studies); in females 60 to 85 yo with cardiovascular risk factors; and in males and females >50 with a first-degree relative with AAA.

<tbody>
<tr>
<td>Obese males, smokers or with a significant Hx of smoking, Hx of myocardial infarction, claudication, having a first relative with AAA, and presence of hypertension. Day 24-227</td>
<td>• Ultrasound monitoring: Yearly screening recommended if AAA between 3.0 and 4.4 cm (possibly every 6 mo if AAA is between 4.0 and 4.4 cm).</td>
<td></td>
</tr>
<tr>
<td>Physical exam including abdominal inspection, auscultation, percussion, &amp; palpation; and peripheral vascular exam. However, clinical exam cannot be relied upon to exclude AAA, especially in smaller AAAs &amp; if abdominal girth &gt;100 cm. Day 226,228</td>
<td>• Referral to a vascular specialist: Recommended if AAA &gt;4.4 cm (measures based on US or CT).</td>
<td></td>
</tr>
<tr>
<td>• Annual rupture rate of small AAA (≤4.5 cm) is 1%-3%.</td>
<td>• Surgical intervention: Recommended if AAA ≥5.5 cm or growth of &gt;0.6 cm to 0.8 cm/y.</td>
<td></td>
</tr>
<tr>
<td>• Annual rupture rate and death from AAA &gt;5.5 cm is 16%, compared with perioperative mortality of 2%-6% (or lower) for open repair. Day 231</td>
<td>• SMT: Relative risk of high velocity, low amplitude (HVLA) lumbar spine manipulation currently undetermined. Day 232</td>
<td></td>
</tr>
<tr>
<td>Atherosclerosis accounts for 90%-95% of AAA, with the remainder predominantly the inflammatory type. AAAs may be defined as a permanent focal dilation of 1.5 times its normal diameter or an expansion of the aorta measuring ≥3.8 cm on the lateral view measured between the most distant calcified borders, usually between the renal artery (L2) and the iliac bifurcation (L4). Common iliac arteries are often involved. Day 232,229</td>
<td>• It is vital to recognize the S&amp;S of dissecting AAA as this is a surgical emergency.</td>
<td></td>
</tr>
<tr>
<td>Risk factors Day 225,230-234. 1. Abdominal aortic aneurysms (AAA): Male sex, cigarette smoking, a first-degree relative with AAA, hypercholesterolemia, and connective-tissue diseases (eg, Marfan, Ehlers-Danlos). 2. Aneurysm expansion risk factors: Advanced age (&gt;70 y), cardiac/renal transplant, previous stroke, severe cardiac disease, tobacco use. 3. Risk factors for aneurysm rupture: Increases with age (age ≥60) and aneurysm size (diameter ≥5.5 cm); current smoking and high mean blood pressure.</td>
<td>• Because of its speed and proximity to emergency department, CT, helical CT, and CTA are imaging of choice to determine the presence and size of the aneurysms, as well as to R/O a ruptured AAA in a clinically stable patient.</td>
<td></td>
</tr>
<tr>
<td>• MRI with MRA also plays an important role, particularly when patient is unable to receive intravenous contrast medium.</td>
<td>• Conventional angiography is used as a secondary diagnostic tool to clarify equivocal findings.</td>
<td></td>
</tr>
<tr>
<td>• Conventional angiography is used as a secondary diagnostic tool to clarify equivocal findings.</td>
<td>• US is helpful when CT is not readily available or patient is too unstable to undergo MRI.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**
- **Truncal symptoms attributed to presence or worsening of aortic aneurysms including dissection/rupture/occlusion or traumatic aortic injury:** Cardiovascular shock and/or syncope, severe, tearing/ripping midabdominal sensation, back, groin, or testicular pain; pressure upon lumbar spine causing excruciating boring pain in the abdomen or back; hypotension; absence of distal lower limb pulses. Day 24-226,241,242
- **Emergency referral without imaging [GPP]** It is vital to recognize the S&S of dissecting AAA as this is a surgical emergency.
- **Evaluation of acute aortic conditions including dissection/rupture/occlusion or traumatic aortic injury** Day 225,243.
- At least 25% of AAAs >5 cm will rupture within 5 y, and those <5 cm have a rupture rate of about 5%. Day 226.

<th>Recommendations</th>
</tr>
</thead>
</table>
| • Only about one third of all affected women in the community have the severe vertebral deformities most likely to produce chronic symptoms including height loss, kyphosis and postural changes, and persistent pain interfering with daily activities. 

Risk factors for additional vertebral fractures:
1. History of a previous fracture (4-fold among postmenopausal white women);
2. Greater age;
3. Lower femoral neck bone mass density (BMD);
4. Shorter height.

Special investigations [D]
Radiographs are unreliable for assessment of bone mass changes before at least a 30%-50% loss. [226] [B]

Suspected osteoporosis
Osteoporosis predisposing risk factors
Include nonmodifiable (age, sex, and period of amenorrhea as in anorexia nervosa and female athlete) and modifiable factors (dietary calcium intake, low BMI, smoking, inactivity, parental Hx of fracture, and high alcohol intake). See Appendix C(4) for a list of other important risk factors.

Osteoporosis clinical decision rules:
Several highly sensitive clinical decision rules based on weighted indices and major osteoporosis risk factors have been developed to identify women with low bone mineral density in need of DXA. [206,206-207]

1. In healthy peri- and early postmenopausal women (45-64 yoa), consider using the OST score (Osteoporosis Self Assessment Tool). OST score considers only 2 variables: (weight in kg – age)/5. The cut-off for a positive test is <2. Indicating this woman should be referred for DXA.

2. In higher-risk patients, use either the ORAI (Osteoporosis Risk Assessment Instrument), the more complex calculation of SCORE (Simple Calculation of Osteoporosis by Estimation) or the AMMED as all 3 were found to be highly sensitive clinical tools. See Appendix C(4) for details.
   a. ORAI considers age, weight and estrogen use;
   b. SCORE considers 6 variables (race, presence of RA, history of fracture, age, estrogen, weight [in pounds]);
   c. AMMED considers 5 variables (age, years after menopause, age at menarche, BMI).

<table>

<tr>
<th>Recommendations</th>
<th>Comments</th>
</tr>
</thead>
</table>
| Age-adjusted incidence rates for clinically evident vertebral fractures in women are twice those in men, partly due to their greater liability to falls. 

 lifetime risk of clinically evident osteoporotic fracture among postmenopausal North American white women >age 50 has been estimated at 40% (vertebrae 15.5%; wrist 16%; hip 17.5%) [24,278] and at 22% in men. [279] The incidence of osteoporotic fractures is increasing and the spectrum of fractures is changing. Fractures of the proximal femur, proximal humerus, pelvic, and many fractures around the knee should also be considered osteoporotic fractures. [280] Vertebral pseudarthrosis, a rare posttraumatic vertebral delayed collapse resulting in bone ischemia, may cause vertebral instability: look for an intravertebral cleft containing gas. These patients tend to have ongoing back pain despite conservative care, severe pain during motion. [235] In suspected fracture:

• Consider MRI or CT if initial radiographs are positive for fracture, equivocal, in the presence of complex lesions, for suspected ligamentous instability or neural injuries. Small fractures can also go undetected on CT scans. [281] 

• NM or MRI may be used to determine if fracture is recent or not, as it may impact on treatment. (NM has a 72-hour delay in elderly patients.) [63] There is a concern that spinal manipulation (HVLA) [282,283] and spinal mobilization [281,284] could cause fractures in individuals with osteoporosis. Spinal manipulation is generally regarded as a relative contraindication in osteoporotic patients. [219,285-287] However, in vitro studies and some case reports suggest forces generated in some manual techniques may be lower than the load required for vertebral failure (fracture) in this population. [273,281] A number of control strategies are available that allow treatment to be applied safely and effectively. [288] When DXA results are unavailable, use clinical decision rules to estimate the presence of osteoporosis. See Appendix C(4) for details.

In suspected osteoporosis
• Bone densitometry or dual-energy x-ray absorptiometry (DXA) recommended in the presence of osteoporotic fractures or with positive osteoporosis clinical decision rules (elevated risk of osteoporosis). DXA is considered the gold standard for bone mass evaluation in the diagnosis and treatment of osteoporosis (DXA >2.5 SD). In postmenopausal females, each SD decrease in lumbar spine BMD increases the risk of any fractures by 1.5-fold and of new vertebral fracture by 2.3-fold. Lateral DXA also accurate for thoracic spine evaluation. [233,284] Of interest:

• Advanced atherosclerosis of the abdominal aorta is associated with lower bone mass density, accelerated bone loss, and increase risk of incident fractures at the proximal femur. Findings in the lumbar spine have been inconsistent. [289]

<tr>
<td><strong>Physical examination and osteoporosis:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>When likelihood of significant osteoporosis is low according to clinical decision rules, examination may include asking patient to rise from a chair and to bend forward at the trunk as vertebral fracture risk associated with loading activities increases risk by about 8- and 10-fold respectively compared with upright standing.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>It should be noted, however, that vertebral tolerance to PA thoracic compressive forces is much less than axial loading. Simple physical tests that could assist in determining ability to tolerate thoracic spine SMT would be useful.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Quality of life among adults with vertebral osteoporosis may be measured using a self-administered questionnaire such as the one from the European Foundation for Osteoporosis (QUALEFFO).</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Adult patient with nonpainful and nonprogressive scoliosis</strong></td>
<td>Radiographs not routinely indicated [C]</td>
<td>In a skeletally mature patient, scoliosis is defined as a spinal deformity with a Cobb angle of &gt;10° in the coronal plane.</td>
</tr>
<tr>
<td>The prevalence rate in healthy adults is &gt;30% and may be as high as 68% in the elderly. Untreated adults with late-onset idiopathic scoliosis (LIS) are productive and functional at a high level at 50-year follow-up. Untreated LIS causes little physical impairment other than back pain (most only have minimal or moderate back pain) and cosmetic concerns. Patients with nonpainful and nonprogressive scoliosis are unlikely to benefit from repeat evaluation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Adult patient with painful or progressive scoliosis</strong></td>
<td>Radiographs indicated [B]</td>
<td>Full spine radiograph for scoliosis to determine other areas of implication</td>
</tr>
</tbody>
</table>
| Some patients with known scoliosis may present with significant disability. Back pain is the most common clinical problem presenting as a multiformal mosaic of symptoms. Constant & nonspecific back pain has a poor prognosis. Other S&S: Radicular pain & claudication when standing or walking (from nerve traction or compression), neurologic deficit may include sphincter dysfunction. Curve progression needs monitoring. | Erect sectional radiographs (better detail) or standing full-length PA (14 x 36 in) and lateral sectionals | a. Cobb angle  
   b. Nash-Moe method (pedicle rotation)  
   NB. Consider ± 5° measurement error |
| **Clinical evaluation:** Look for spinal deformity, uneven shoulder heights, limb length inequality, pelvic obliquity, hip pathology, and claudication. Neurologic exam includes nerve root tension signs, motor power, sensations, deep tendon reflexes, and pathological reflexes. | | Clinically relevant radiographic parameters in adult scoliosis including lateral vertebral listhesis, L3 and L4 endplate obliquity angles, increased lumbar lordosis and thoracolumbar kyphosis significantly correlated with pain, sagittal imbalance & significant coronal imbalance of >4 cm, lapsed spondylolisthesis (lateral translation & vertebral rotation) may cause radicular pain syndrome. |
| 1. Adam’s forward bend test is sensitive to detect trunk asymmetry  
2. Maximal lateral flexion into convexity to evaluate curve functional aspect.  
3. Scoliometer (a trunk angle of 7° indicates a structural curve <20°). | | Types of lumbar scoliosis may be classified according to the lordosis and L3 obliquity. Self-reported pain & disability may increase with increasing scoliosis type (from 1 to III). |
| **Spinal deformity has an important impact on the general health status of adults as measured by the Medical Outcomes Study Short-form 36 (SF-36) and the modified Scoliosis research Society Outcome instrument (SRS-22).** The SRS-22 is a disease-specific instrument assessing pain, self-image, function, mental health, and satisfaction. It is a valid, reliable, and reproducible outcomes instrument for adult deformity. | | a. Most commonly used to determine fusion levels. May help differentiate between structural and nonstructural curves and help assess primary from secondary scoliotic curves. |
| **Adult degenerative scoliosis:** pathomechanism includes a viscous cycle of asymmetric degeneration (disc & facet joints) leading to asymmetric loading, leading to asymmetric deformity which in turn triggers asymmetric degeneration and leading and enhancing curve progression. | | |

<th>Patient presentation</th>
<th>Standards of care dictate that careful history and physical examination be done routinely for all patients on the initial visit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Most neck pain is not the result of serious disease. Factors associated with neck pain include:</td>
<td>Headache</td>
<td>Self-reported patient assessment to evaluate perceived pain, function, disability, and psychosocial status are recommended.</td>
</tr>
<tr>
<td>- Low back pain</td>
<td>Poor psychological health</td>
<td>The validity and utility of the clinical assessment (history and examination) in patients with neck pain with no radiculopathy or red flags needs to be confirmed.</td>
</tr>
<tr>
<td>- History of whiplash injury</td>
<td>Poorer general or self-rated health</td>
<td>Diagnostic tests such as X-rays, CT or MRI scans are only required in a minority of cases when a thorough physical examination and patient history indicate further investigation is needed. Routine imaging is unlikely to increase understanding of causation.</td>
</tr>
<tr>
<td>- Possibly cigarette smoking</td>
<td>In patients presenting with head and/or neck pain, the physical examination should flow as a natural extension of the information obtained from the chief complaint, history, and system review. (see Honet and Ellenberg for a review of history &amp; physical examination for neck pain).</td>
<td>Neck pain on initial presentation is typically classified according to the duration of complaint and type of presentation: uncomplicated/nonspecific neck pain, with or without restriction of activity of daily living, presence of neurologic deficits or to some underlying pathology.</td>
</tr>
<tr>
<td>- In complaints of neck and arm pain, peripheral (weakness, dermatomal pattern, and loss of deep tendon reflexes) and central nervous system exam (clonus, Babinski, and pathological reflexes) should be an integral part of initial examination. Findings of long tract signs mandate further evaluation.</td>
<td>In patients presenting with head and/or neck pain, the physical examination should flow as a natural extension of the information obtained from the chief complaint, history, and system review. (see Honet and Ellenberg for a review of history &amp; physical examination for neck pain).</td>
<td>Neck pain affects nearly two third (66.7%) of the adult population over their lifetime representing a significant and costly health problem in terms of care, suffering, and work absenteeism. Contrary to prior belief, most individuals with neck pain do not experience complete resolution of their symptoms and disability.</td>
</tr>
</tbody>
</table>

Duration of complaint:
- Acute neck pain: <4 wks’ duration
- Subacute neck pain: 4-12 wks’ duration
- Persistent/chronic neck pain: >12 wks’ duration

The age-standardized 6-month point prevalence is around 22% with nearly 40% having low-intensity and low-disability neck pain, 10% having high-intensity and low-disability neck pain and 4.6% (95% CI, 3.3-5.8) having disabling pain.
**Table 5 (continued)**

<table>
<thead>
<tr>
<th>Patient presentation</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>• In headache complaints, vital signs (to R/O severe hypertension or fever) and testing of the cranial nerves (to R/O vascular events, space occupying lesions, etc) should be an integral part of initial examination. Significant positive findings mandate further evaluation.</td>
<td>The age and sex annual incidence of neck pain is 14.6% (95% CI, 11.3-17.9) and each year, 0.6% develop disabling neck pain. Annual course of neck pain is as follows: 36.3% resolve and 32.7% improve. Among neck pain sufferers, 33.3% report persistent problems, 9.9% get worse, and 22.8% recur. Between 22% and 25% of initial chiropractic visits are for neck-related complaints. Although most patients seeking chiropractic care experienced their symptoms for &lt;3 wk (45%), over 20% had symptoms for &gt;6 mo. In addition, 5%-6% of chiropractic patients consult for headache. Neck pain is slightly more common in females and increases with age, the mean age being in the early 40s. Not surprisingly, these figures parallel the most common age range seeking consultation for chiropractic spinal manipulative therapy (61% of females; mean age of 42 years old).</td>
</tr>
<tr>
<td>• In suspected connective tissue disorders, examination should also include inspection of the integument (skin elasticity, discoloration), the back (scoliosis), the thorax (deformity, abnormal respiratory pattern), and extremities (disproportion), auscultation of the heart (valvular defect) and abdominal aorta (bruit), abdominal palpation (organomegaly in fibromuscular dysplasia-kidney, aorta), and musculoskeletal examination including peripheral joint laxity using the 1998 Beighton criteria and examination of chronic joint and limb complaints.</td>
<td>Auscultation of the neck and the use of common premanipulation vascular screening tests (eg, Houles, George, etc) are of no diagnostic value. Functional vascular tests may themselves put patient at risk of a serious complication.</td>
</tr>
<tr>
<td>Adult patient with acute uncomplicated* neck pain (&lt;4 wks’ duration)</td>
<td>Radiographs not routinely indicated [C]</td>
</tr>
<tr>
<td>• Definition of “uncomplicated”: nontraumatic neck pain without underlying neurologic deficits or red flag (see red flags list for details).</td>
<td>The clinical value of conventional radiographs for nontraumatic acute neck pain without red flags or arm pain is not well established. Acute neck pain is generally due to conditions that cannot be seen on conventional radiographs. The clinical significance of the cervical spine curvature remains controversial. Consider cervical radiography, advanced imaging studies, and a second opinion in the absence of expected treatment response or worsening after 4 wk.</td>
</tr>
<tr>
<td>Adult patient with nontraumatic neck pain and radicular symptoms</td>
<td>Radiographs indicated [D/consensus] APOM, AP lower cervical, neutral lateral</td>
</tr>
<tr>
<td>May be caused by HNP, spondylosis, and rarely by other pathological processes (tumor, abscess, etc).</td>
<td>Disc lesions cannot be visualized on radiographs. IVF narrowing by facet &amp; uncinate process hypertrophy are very often associated with radicular symptoms. Spinal stenosis (sagittal diameter &lt;13 mm) may also be present, in which case specific comments should be taken if manual therapy is considered. Always examine the patient’s lower extremities for upper motor neuron signs indicating cervical radiculopathy. Hoffman sign, lower limb hyper-reflexia, spasticity, Babinski, and/or Clonus. Clinical diagnosis of CDH possible in only 50%-75% of cases of cervical radiculopathy as a wide variation of presentations exists even with only one nerve root involved (C6 more common than C7 which is more common than C8 level). Patients should be monitored and S&amp;MS should progress in the first 2-3 wk.</td>

- Significant activity restriction >4 wk
- Nonmechanical pain (unrelenting pain at rest, constant or progressive S&S)
- Neck rigidity in the sagittal plain in the absence of trauma (discitis, infection, tumor, meningitis, etc);
- Dysphasia;
- Impaired consciousness;
- Central nervous system S&S (cranial nerves, pathological reflexes, long tract signs);
- High risk ligament laxity populations/suspected atlantoaxial instability (see details below);
- Arm or leg pain with neck movements;
- Suspected cervical myelopathy and radiculomyelopathy (see details below);
- Sudden onset of acute and unusual neck pain and/or headache (typically occipital) with or without neurologic symptoms, suspected cervical artery dissection (VAD, CAD), TIA (VBI, carotid artery ischemia), stroke (see details below);
- Hx of severe trauma (see Trauma section).

In addition, also consider general red flags (relative utility and cost-effective of screening patients for non traumatic neck pain for serious structural disease (“Red Flags”) need to validate) which may apply to the cervical spine

- **Suspected neoplasia:** considerable pain starting >age 50; Hx of cancer/carcinoma (in the last 15 y) or failure of conservative care (4 wk), lymphadenopathy; dermopathy (melanoma). S&S of cervical spine tumors tend to be variable (slight pain, neck stiffness, scoliosis, presence of a mass and/or severe neurologic deficit). Night pain remains a classic indicator of nonmechanical neck pain and neoplasm. Other systemic symptoms may include unexplained weight loss (>10 lb over 4 wks) and systemically unwell.

- **Suspected infection (discitis, osteomyelitis, tuberculosis):** documented fever (>38.3°C/101°F) for >3 wk and no established diagnosis despite appropriate investigation for 1 week; elevated ESR >20 mm/h; IV drug abuse; immunosuppression (HIV, transplant patients); UTI, skin infection, diabetes mellitus; alcohol abuse; vertebral tenderness with underlying infection; direct implantation (nail, acupuncture); Hx of spine surgery.

- **Suspected failed surgical fusion:**
- **Progressive or painful structural deformity:**
Table 5 (continued)

<table>
<thead>
<tr>
<th>Patient presentation</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abnormal laboratory examination and positive S&amp;S: ESR &gt;50 mm/h; RA factor; HLA-B27; BCB; ALP; PSA; serum calcium, for example,(^{2,1,2})</td>
<td>In whites, the prevalence of RA is 0.8%-1%. Cervical spine involvement occurs in over half of patients with RA, and atlantoaxial subluxation (AAS) develops in over 12% of patients with RA. There is a strong correlation between a Larson erosion score for hand &amp; wrist joint damage &gt;50, RA duration of &gt;10 y, disease onset before age 50, number of previous drug modifying disease and RA-related surgery and AAS. It is important to recognize that many patients acquire AAS in the first 3 y of their disease, but neurologic impairments develop after a mean period of 18 y (range, 4-50). RA patients with AAS have a higher mortality rate compared those without AAS.(^{3,4,6,7,9,10})</td>
</tr>
<tr>
<td>Note: It may be reasonable to consider many of the lumbar spine red flags in complaints of neck pain. However, their level of evidence as such is currently unknown.^^(^{15})</td>
<td></td>
</tr>
</tbody>
</table>

1. Suspected atlantoaxial instability (AAS):
   High-risk ligament laxity populations/possible atlantoaxial instability include\(^{6,2,2,9,2,5,7,3,6}\).
   (a) Active inflammatory arthritis: known rheumatoid arthritis (RA), psoriatic arthropathy, chronic juvenile RA, and less commonly in AS (2% of cases). S&S of presumed inflammatory spondyloarthropathy include significant morning stiffness (>1 h); pain duration ≥3 mo; persisting motion restriction; gradual onset ≤age 40; peripheral joint involvement; UTI, urethral discharge, iritis, skin rash.\(^{34}\)
   (b) Congenital disorders & hereditary connective tissues disorders such as dysplasia, os odontoideum, Klippel-Feil, Morquio's, Down's syndrome (20% are born without a transverse ligament), Ehlers-Danlos syndrome type III, Marfan syndromes.

Screening for high-risk ligament laxity populations is important for manual therapists. Little is known about the value of commonly used manual tests. Although agreement and reliability between 2 examiners is difficult to achieve for general cervical spine mobility & interssegmental passive mobility,\(^{26}\) acceptable levels of predictive value, sensitivity, and specificity have been reported for the Sharp-Parser test.\(^{220}\) Cattrysse et al\(^{266}\) were not able to reproduce such results in a small group of children with Down's syndrome, however. Preliminary data support the use of the upper cervical flexion test for those patients.

Radiographs indicated [B]
APOM, AP lower cervical, neutral lateral

Special investigations [C]
Additional views [D]
a. Flexion/extension laterals.\(^{49}\)

2. Suspected cervical compressive myelopathy (CCM) and radiculo-myelopathy

Causes of cord compression include trauma, tumors, infection, vascular disease, degenerative conditions, degenerating disorders, spinal stenosis, & central cervical disc herniation.

Cervical spondylotic myelopathy (CSM)\(^{25,3,7,2-3,75}\)
1. MC >50 y;
2. Variable neurologic deficit of upper (hyporeflexia) and lower extremities (hyperreflexia); axial skeleton sensory and motor dysfunction that skip the head & face;
3. Arm or leg pain with neck movements;
4. Long tract signs and pathological reflexes (Clonus, Babinski, Hoffman); Lhermitte's sign (cervical flexion and extension producing electrical shocks down the arm and leg);
5. Subtle gait abnormality (loss of balance, spasticity, unsteadiness, loss of leg power, broad base, shuffle and disruption in smooth, rhythmic function);

Radiographs indicated [C]
APOM, AP lower cervical, neutral lateral, and bilateral oblique views.

Additional views:
Swimmer's view

For cervical spondylotic myelopathy, patients should be treated conservatively if they have a spinal transverse area >70 mm\(^2\), are of older age, and have normal central motor conduction time. Surgery is more suitable for patients with clinically worse status (function expressed as modified Japanese Orthopaedic Association score and slower walk) and a smaller transverse area of spinal cord.\(^{3,7,6}\)

Central spinal stenosis, acute cervical myelopathy, and/or radiculo-myelopathy is generally considered a contraindication for manual therapy although some patients with nonacute & nonprogressive S&S have safely received such intervention. Caution is advised in those patients as even minor trauma in patients with preexisting severe spondylosis has potentially serious consequences.\(^{1,3,6,3,7,3,9,3,4,3,5,7,3,8,5}\)

Consider Swimmer's view if symptoms are located in cervicothoracic junction or if this area is not well visualized on lateral view.

a. A sagittal diameter <13 mm indicates spinal stenosis and is critical for the development of a cervical

(continued on next page)
Neurologic examination in patients with CSM is moderately accurate and reliable for determining the neurologic level of disease. Among the neurologic tests (deep tendon reflex, pinprick response, muscle weakness, and numbness in the hand only), patient-perceived location of numbness in the hands may be the most useful for establishing the affected level.\(^ {374} \)

### Special investigations [C]

#### 3. Suspected cervical artery dissection (VAD, CAD), TIA (VBI, carotid artery ischemia), stroke.

In most cases, there is little that could prospectively alert even the astute practitioner to an impending vascular event. Most patients are young, apparently healthy individuals, suffering from musculoskeletal complaints without any predisposing stroke risk factors.

The most important points in the history and chief complaint, which would warn of a possible cervical artery disease, are:\(^ {308,318,354,387,388} \)

- a. S&S of VBI—the “5D’s and 3 N’s”: dizziness, dysphasia, dysarthria (hoarseness), drop attacks, diplopia (or other visual problems), ataxia of gait (hemiparesis), nausea (possibly with vomiting), numbness (herniaesthesia), nystagmus.
- b. S&S of carotid artery ischemia/stenosis: confusion, dysphasia, headache, anterior neck and/or facial pain, herniaesthesia, hemiparesis or monoparesis, visual field disturbances.
- c. Neck or occipital pain with sharp quality and severe intensity or severe & persistent headache that is sudden and unlike any previous experienced pain or headache (even when it is suspected the pain is of a musculoskeletal or neuralgic origin)

#### Emergency referral without imaging [GPP]

Urgent referral should be made for appropriate investigation and treatment in patient presenting S&S of cerebrovascular ischemia or when S&S of head/neck pain is suspicious for an acute cervical artery disease. Initial investigation often includes CT scan of the brain to R/O hemorrhagic stroke.

#### Additional information:

- a. Sudden onset of acute and unusual headache and/or neck pain is present in 92% of cases of cervical artery dissection and may occur either spontaneously, after a specific activity, a significant neck trauma, or after cervical spine manipulation.
- b. Immediate or delayed neurologic S&S developing spontaneously, after a specific activity, a significant neck trauma, or after cervical manipulation; including the 5 D’s and 3 N’s are absolute contraindications to SMT.
- c. S&S of internal carotid artery dissection: most common presentation: headache and neck pain (90%), ischemic symptoms (50%-95%), Horner’s syndrome (<52%), visual scintillation (3%), monocular blindness (6%-30%), subjective bruit (25%-48%), impairment of taste (10%-19%).\(^ {302} \)

#### Special investigations [C]

Appropriate consultation and/or diagnostic procedures to evaluate the status of the cerebral circulation required in patients presenting with significant risk factors for cervical artery dissection. In such cases, approach the treatment with caution until a specific determination is made.\(^ {308,318} \)

#### Should cervical artery problems be suspected, a thorough workup is indicated which may include:\(^ {345} \)

- • Gold standard diagnostic tests (MRA/MRA) should be performed before implementing any manipulative procedure.\(^ {308} \)
- • US imaging of the cervical vessels is typically used as a fast, noninvasive screen when pathology is suspected. Color-coded duplex ultrasonography can help diagnose vertebral artery (VA) occlusion and VBI by measuring blood flow velocity & flow volume and diameter of the VAs (including hypoplasia & asymmetry).\(^ {354,403,406} \)

However, US is operator dependant, lacks resolution, and has some limitations associated with vertebral artery evaluation. For these reasons, ultrasound may not be a viable screening tool.\(^ {407,409} \)

<tbody>
<tr>
<td>6. Bowel &amp; bladder dysfunction (rare).</td>
<td>radiculomyelopathy, even in the presence of mild degenerative spondylosis (normal is 17-18 mm between C3-C7). Caution is recommended if AP diameter &lt;11 mm and manual therapy is contemplated.(^ {318} )</td>
</tr>
</tbody>
</table>
| Neurologic examination in patients with CSM is moderately accurate and reliable for determining the neurologic level of disease. Among the neurologic tests (deep tendon reflex, pinprick response, muscle weakness, and numbness in the hand only), patient-perceived location of numbness in the hands may be the most useful for establishing the affected level.\(^ {374} \) | b. A Torg’ or Pavlov ratio (spinal canal/vertebral body) <0.8 indicates spinal stenosis.\(^ {354,387,388} \)

**NB.** It is important to recognize that conventional radiography may not be very reliable to determine central canal stenosis as there is some variation in the size of the spinal cord and stenosis may be due to nonosseous factors (ligamentum flavum, cartilage hypertrophy etc).

Refer patient for investigation and possible surgical intervention:

1. After failed conservative therapy (4 wk);
2. If neurologic status is deteriorating (progressive deficit, disabling arm pain);
3. For preoperative planning;
4. MRI (CT-myelography if MRI not available) Electrophysiologic testing such as somatosensory-evoked potentials (SSEF) may be useful.

Emergency care:

It is vital to recognize the S&S of cerebrovascular ischemia and stroke in which case patient must be referred immediately to emergency facility for early and appropriate treatment.

---

**Comments**

Any reports consistent with TIA's, prior stroke history (1% risk of recurrence/year), severe hypertension (noted in half of cases of spontaneous/idiopathic vertebral artery dissection), Hx of a major cervical spine trauma (attributed to 10% of vertebrobasilar syndrome), cardiac abnormalities that predispose to thrombus formation or myotic arteriopathy should prompt close observation for neurologic status.\(^ {308,318,389,390} \)
Table 5 (continued)

<table>
<thead>
<tr>
<th>Patient presentation</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Although several risk factors have been proposed for cervical artery dissection, ( ^{308,318,385-399} ) current literature does not assist in identification of precipitating causes. VBIs may be considered the result of cumulative events over time/multifactorial. ( ^{400,401} ) The patient history should include a system review and family history.</td>
<td>• Catheter digital angiography is an invasive procedure with associated risk of stroke (( \approx 1% )). MRI/MRA considered method of choice as initial diagnosis and follow-up of craniocervical artery dissection.</td>
</tr>
</tbody>
</table>

**Further consideration**

- Catheter digital angiography is an invasive procedure with associated risk of stroke (\( \approx 1\% \)). MRI/MRA considered method of choice as initial diagnosis and follow-up of craniocervical artery dissection.

See Mullins\(^{609} \) and Foerster et al\(^{245} \) or a review on stroke imaging

**Further considerations**

1. External structures such as facet & uncovertebral joint osteophytes and presence of a retroarticular canal may potentially compress the vertebral artery.\(^{410-412} \) However, no cases were found to be associated with either retroarticular canal or posterior ponticle in young adults.\(^ {258} \) Although 1 case of VBI and one stroke have been associated with vertebral artery stenosis from osteophytes, cervical spondylosis does not appear to increase the risk of vertebrobasilar accidents after vertebral manipulation. If such were the case, one would expect older patients (>45 yoa) to be at heightened risk, but they are not.\(^ {258-290} \) There is currently no evidence that in the absence of red flags in the adult patient, routine cervical spine radiographs before initiating manipulative therapy have any value as a mean to reduce rare, random, unpredictable vascular complications associated with neck movement, trivial trauma, or cervical manipulation.\(^ {308,318,390} \)

2. Limiting neck rotation during SMT and applying the smallest force required to achieve therapeutic objective is advisable.\(^ {311,413} \)

3. Migraine headache is a risk factor for stroke in young patients. When possible, treat all stroke modifiable risk factors aggressively, especially in women over age 35: smoking, oral contraceptives, presence of aura, >12 attacks of migraines/year, >12 y of migraine history.\(^ {414} \)

4. Tests and imaging studies that would help screen patients at risk of adverse vascular events before receiving cervical SMT would be of great help. However, such studies are not available presently.\(^ {308} \) There is currently no evidence that in the absence of red flags, routine cervical spine radiographs before initiating manipulative therapy have any value as a means to reduce rare, random, unpredictable vascular complications associated with neck movement, trivial trauma, or cervical manipulation.

5. In patients with past a history of major trauma to the cervical spine*, MRA or angiography recommended before treating the neck as follow-up MRA indicates that these damaged vertebral arteries usually do not recanalize.\(^ {415-421} \)

In a review of 80 cases of traumatic vertebral ischemia, MVA were thought to be responsible for 77.5% of cases, with delays between trauma and the onset of neurologic S&S of up to 5 y. The severity of trauma caused loss of consciousness (LOC) in 70% either at the time of injury or with subsequent episode of vertebrobasilar ischemia and short-term memory deficit in 64%. However, severity of trauma was mild for many, with no LOC, and no blow to the head.\(^ {422} \)
ARE THERE POTENTIAL RISKS ASSOCIATED WITH
CONVENTIONAL RADIOGRAPHS?

Although somewhat controversial,\textsuperscript{20-23} it is important to remember that health hazards of all forms of radiation are cumulative.\textsuperscript{25-30} The Biological Effects of Ionizing Radiation (BEIR) 2005 report released by the National Academy of Sciences adds further support to the "linear-no-threshold" model of cancer risk from ionizing radiation exposure.\textsuperscript{31} In summary, this report concludes that ionizing radiation is dangerous even at low doses and that there are no safe limits. Given the potential risks associated with conventional radiographs, only appropriate clinical indications can justify its use. In this regard, the need to confirm pathology, to follow the evolution of a pathology possibly affecting therapy, or to identify a clinically suspected contraindication to manipulative therapy is the best-documented reason. The benefits of all diagnostic studies must outweigh the risks and the inherent costs to the patient.\textsuperscript{10,32-40}

Tables 1-5 list the patient presentations, recommendations, and comments regarding diagnostic imaging for spine disorders. A list of abbreviations and glossary of terms used in the recommendations is in Appendix A. Appendix B provides a summary of the recommendations. Pertinent information for spinal disorders is presented in Appendix C. General indications for advanced imaging are in Appendix D. Typical effective ionized radiation dose for common imaging procedures is listed in Appendix E. Further recommended reading pertaining to magnetic resonance imaging of the spine is offered in Appendix F.

ACKNOWLEDGMENT

We appreciate the efforts of the many people who assisted in this process, listed in Appendix G.

SUPPLEMENTARY DATA

Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.jmpt.2007.10.003 and in tables D1-D3 in Appendix D of Reference 2.

REFERENCES

Practical Applications

- History taking and physical examination to exclude underlying sinister cause (red flags) and serious injuries (fracture and/or dislocation)
- Physical examination for signs of nerve compression
- Diagnostic triage (non specific back, neck, and extremity pain, with or without restriction of activity of daily living, radicular syndrome, presence of red flags)
- Radiographs not initially indicated for non specific acute, subacute, or persistent back and neck pain (no red flags)
- Consider conventional radiography after blunt trauma (according to decision rules), and if there is no improvement after 4-6 weeks of conservative care or increasing disability
- Consider conventional radiography and specialized imaging for radicular syndrome and presence of red flags
- Urgent specialized imaging for back and neck pain with adverse features: sphincter or gait disturbance, saddle anesthesia, severe or progressive neurologic deficit, systemic illness (cancer, infection), vascular causes (suspected abdominal/thoracic aorta aneurysm), or cervical artery dissection.

APPENDIX A. LIST OF ABBREVIATIONS AND GLOSSARY FOR SPINE DISORDERS

AAA: Abdominal aortic aneurysms

AAS: Atlantoaxial subluxation

ACR: American College of Radiology

ALP: Alkaline phosphatase (if elevated, R/O cancer, infection Paget’s disease)

AP: Anteroposterior

APOM: Anteroposterior open mouth

AS: Ankylosing spondylitis

BMI: Body mass index

CES: Cauda equina syndrome

CNS: Central nervous system

CAD: Cervical artery dissection

CI: Confidence interval

CT: Computed tomography (advanced imaging modality that uses ionizing radiation [Table 1]. Generally considered to be the gold standard imaging for the chest, abdomen, pelvis, complex osseous anatomy, or in musculoskeletal disorders when contraindications for MRI exist).
CTA: Computed tomography angiography
DDx: Differential diagnosis
Dx: Diagnosis
ESR: Erythrocyte sedimentation rate (if elevated, R/O inflammation due to cancer, infection, fracture)
GHQ-28: General Health Questionnaire
GPP: Good Practice Point
HNP: Herniated nucleus pulposus/disc herniation
Hx: History
IVF: Intervertebral foramen
JRA: Juvenile rheumatoid arthritis
LBP: Low back pain
LDH: Lumbar disc herniation
LOE: Level of evidence
MC: More common
Mo: Month
MRA: Magnetic resonance angiography—gadolinium enhanced
MRI: Magnetic resonance imaging (generally considered to be the best single advanced imaging modality of the spine to confirm or exclude most clinically relevant findings after conventional radiographs)
NM: Nuclear medicine (also known as bone scan or scintigraphy) uses a radiopharmaceutical and gamma camera to produce a physiologic skeletal survey (Table 1). Has high sensitivity but low specificity.
NDI: Neck Disability Index
PA: Posteroanterior
PSA: Prostate-specific antigen (R/O prostate cancer)
Red Flag: Indicator of potentially serious pathology obtained from history, physical examination, and/or radiographs. Nonspecific/uncomplicated/mechanical neck and back pain are considered diagnoses of exclusion. Patients should therefore be properly evaluated for indicators of potentially serious pathology before undergoing some forms of manual therapy.
RA: Rheumatoid arthritis
Rh factor: Rheumatoid factor (indicates possible rheumatoid arthritis; 2%-5% false positive)
ROM: Range of motion
R/O: Rule out
SLR: Straight leg raise test
SMT: Spinal manipulative therapy—high-velocity, low-amplitude thrust techniques
S&S: Signs and symptoms
TIA: Transient ischemic attack
Tx: Treatment
US: Ultrasound
VAD: Vertebral artery dissection
VBA: Vertebrobasilar accident
VBI: Vertebrobasilar insufficiency
WAD: Whiplash associated disorder
W/O: Without
X-ray: Conventional radiograph
yoa: Years of age
<: Less than
>: Greater than
\geq: Equal to or greater than
\psi: psychology/psychiatry
### Table 1. Summary of Recommendations—Thoracolumbar, Lumbar, and Thoracic Spine Trauma

Table 2. Summary of Recommendations—Cervical Spine Trauma

<table>
<thead>
<tr>
<th>Patient Presentation</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adult patient with acute neck injury and negative CCSR (Canadian Cervical Spine Rule for Radiography in Alert and Stable Trauma Patients)</td>
<td>Radiographs not routinely indicated [B]</td>
</tr>
<tr>
<td>Adult patient with acute neck injury and positive CCSR (Canadian Cervical Spine Rule for Radiography in Alert and Stable Trauma Patients)</td>
<td>Radiographs indicated [B] APOM, AP lower cervical, neutral lateral</td>
</tr>
</tbody>
</table>

Conventional radiographs recommended in the presence of any of the Canadian Cervical Spine Rule criteria are fulfilled:

(A) High-risk factors in alert and stable patient?
1. Age >65
2. Dangerous mechanisms of injury*
3. Parethesias in extremities

(B) Low-risk factors that allow ROM assessment?
1. Simple rear end collision**
2. Patient seated in the waiting room
3. Ambulatory at one time since trauma
4. Delayed cervical pain onset
5. Absence of midline cervical tenderness

(C) ROM assessment: is patient able to actively turn his/her head to 45° in both directions?

Table 3. Summary of Recommendations—Adult Nontraumatic Lumbar Spine Disorders

<table>
<thead>
<tr>
<th>Patient Presentation</th>
<th>Recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adult patient with acute uncomplicated* LBP (&lt;4 wks' duration)</td>
<td>Radiographs not initially indicated [B]</td>
</tr>
</tbody>
</table>

*Uncomplicated definition: nontraumatic LBP without neurologic deficits or indicators of potentially serious pathologies—(see red flag list for details).

For most young or middle-aged adults, early diagnostic evaluation of low back complaints may focus on 3 basic questions: diagnostic imaging is infrequently required (Jarvik 2002).4
1. Is there underlying systemic disease?
2. Is there neurologic impairment that might require surgical intervention?
3. Is social or psychological distress amplifying or prolonging the pain?

Adult patient with uncomplicated subacute (4-12 wks' duration) or persistent LBP (>12 wks' duration) AND no previous treatment trial.
A trial of up to 4-6 wk of conservative care is appropriate before radiographs

Radiographs not initially indicated [B]

Adult patient with nontraumatic acute LBP AND sciatica (no red flags)
The first clinical clue to neurologic impairment usually is a history of sciatica: sharp pain radiating down the posterior or lateral aspect of the leg, often associated with numbness or paresthesia.

Radiographs not initially indicated [B]

**Adult patient reevaluation in the absence of expected treatment response or worsening after 4-6 wk**

Should patient fail to improve as expected or marginally improve within 4-6 wk of initial evaluation, the clinician must review history and physical findings and request appropriate diagnostic imaging studies.

Radiographs indicated [B]
PA (or AP), lateral lumbar views

Additional views not routinely indicated [C]
Spot lateral, oblique, lateral flexion films may be indicated in scoliosis evaluation

Co-management or specialist referral recommended even if conventional radiographs are unremarkable:
1. After failed conservative therapy (4-6 wk)
2. For preoperative planning;
3. If patient’s neurologic status is deteriorating (progressive deficit, disabling leg pain);

- MRI, CT

**Adults with complicated (ie, “red flag”) LBP and indicators of contraindication to SMT (relative/absolute):**

Presence of the following indicator(s) should alert the clinician to possible underlying pathology. Presence of a red flag alone may not necessarily indicate the need for radiology.

- **Patient <age 20 and >age 50, particularly with S&S suggesting systemic disease**

Radiographs indicated [B] PA (or AP), lateral lumbar views.

</tbody>
</table>

• Suspected CES
The classic syndrome includes LBP, bilateral or unilateral sciatica, saddle anesthesia, motor weakness of the lower extremities that may progress to paraplegia, urinary retention, or bowel and bladder incontinence.

• Suspected AAA
Early S&S may include abdominal pain, backache, and feeling of fullness or abdominal pulsation.

• Truncal symptoms attributed to the presence or worsening of aortic aneurysms including dissection/rupture/occlusion or traumatic aortic injury
Cardiovascular shock and/or syncope, severe, tearing/ripping midabdominal sensation, back, groin or testicular pain; pressure upon lumbar spine causing excruciating boring pain in the abdomen or back; hypotension; absence distal lower limb pulses

| Adult patient with uncomplicated* subacute (4-12 weeks duration) and persistent neck pain (>12 weeks) with or without arm pain. | Radiographs not initially indicated* [consensus]  
APOM, AP lower cervical, neutral lateral  
N.B. This recommendation was modified according to the recent findings of The Bone and Joint Decade 2000-2010 Task Force on Neck Pain and its Associated Disorders (see articles published in Spine 2008; 33(4S)). A majority of Delphi panelists agreed with this change (92% of 50 respondents). |
| Adult patient reevaluation in the absence of expected treatment response or worsening after 4 weeks. | Radiographs indicated [C]  
APOM, AP lower cervical, neutral lateral  
**Additional views:** Oblique views, Swimmer's view, Flexion/Extension  
**Comanagement or specialist referral recommended**  
(even if conventional radiographs are unremarkable)  
1. If conventional radiography reveals suspected pathology.  
2. After failed conservative therapy (4 wk),  
3. If patient neurologic status is deteriorating (progressive deficit, disabling arm pain);  
4. If clinical signs suggest subaxial cervical spine instability. (Moore 2006)  
5. For preoperative planning;  
**Special investigations [B]**  
• MRI |
| Adult patient with complicated (ie, “red flag”) neck pain and indicators of contraindication to SMT. Presence of the following indicator(s) should alert the clinician to possible underlying pathology.  
N.B. Presence of a red flag alone may not necessarily indicate the need for radiography.  
• **Patient <age 20 and >age 50, particularly with S&S suggesting systemic disease****  
• No response to care after 4 wk  
• Significant activity restriction >4 wk  
• Nonmechanical pain (unrelenting pain at rest, constant or progressive S&S)  
• Neck rigidity in the sagittal plane in the absence of trauma (discitis, infection, tumor, meningitis, etc);  
• Dysesthesia;  
• Impaired consciousness;  
• Central nervous system S&S (cranial nerves, pathological reflexes, long tract signs);  
• High risk ligament laxity populations/suspected atlantoaxial instability (see details below);  
• Arm or leg pain with neck movements, suspected cervical myelopathy and radiculomyelopathy (see details below);  
• Sudden onset of acute and unusual neck pain and/or headache (typically occipital) with or without neurologic symptoms, suspected cervical artery dissection (VAD, CAD), TIA (VBI, carotid artery ischemia), stroke (see details below);  
• Hx of severe trauma (see Trauma section). | Radiographs indicated [B]  
APOM, AP lower cervical, neutral lateral  
**Additional views:** flexion/extension, oblique views, pillar view  
**Advanced imaging and specialist referral recommended:**  
**Special investigations [B]**  
• MRI |

(continued on next page)
In addition, also consider general red flags (usually applied to LBP) which may apply to the cervical spine

- Suspected neoplasia
- Suspected infection (discitis, osteomyelitis, tuberculosis)
- Suspected failed surgical fusion
- Progressive or painful structural deformity
- Elevated laboratory examination and positive S&S

- Suspected atlantoaxial instability (AAI)
High risk ligament laxity populations/possible atlantoaxial instability include
(a) Active inflammatory arthritides
(b) Congenital disorders and hereditary connective tissues disorders

Radiographs indicated [B]
APOM, AP lower cervical, neutral lateral

Additional views [D]: flexion/extension laterals

Monitoring, advanced imaging and specialist referral recommended:
1. ADI >3 mm, vertical dislocation, lateral, posterior or subaxial subluxations
2. Upward odontoid translocation (pseudobasilar invagination)
3. In presence of neurologic S&S

Special investigations [C]
- CT, MRI

- Suspected cervical compressive myelopathy (CCM) and radiculomyelopathy

Radiographs indicated [C]
APOM, AP lower cervical, neutral lateral and bilateral oblique views.

Additional views: swimmer’s view

Refer patient for investigation and possible surgical intervention:
1. After failed conservative therapy (4 wk),
2. If patient’s neurologic status is deteriorating (progressive deficit, disabling arm pain);
3. For preoperative planning;

Special investigations [C]
- MRI (CT-myelography if not available). Electrophysiologic testing such as somatosensory evoked potentials (SSEP) may be useful.

- Suspected cervical artery dissection (VAD, CAD), TIA (VBI, carotid artery ischemia), stroke
The most important points in the history and chief complaint, which would warn of a possible cervical artery disease, are:

a. S&S of VBI—the “5D’s And 3 N’s”: dizziness, dysphasia, dysarthria (hoarseness), drop attacks, diplopia (or other visual problems), ataxia of gait (hemiparesis), nausea (possibly with vomiting), numbness (hemianesthesia), nystagmus;

b. S&S of carotid artery ischemia/stenosis: confusion, dysphasia, headache, anterior neck and/or facial pain, hemianesthesia, hemiparesis or monoparesis, visual field disturbances.

c. Neck or occipital pain with sharp quality and severe intensity or severe and persistent headache that is sudden and unlike any previous experienced pain or headache (even when it is suspected the pain is of a musculoskeletal or neuralgic origin)

Should cervical artery problems be suspected, a thorough workup is indicated.

Emergency referral without imaging [GPP]
Urgent referral should be made for appropriate investigation and treatment in patient presenting S&S of cerebrovascular ischemia or when S&S of head/neck pain is suspicious for an acute cervical artery disease.

Special investigations [C]
- Initial investigation often includes CT scan to R/O hemorrhagic stroke.

Appropriate consultation and/or diagnostic procedures to evaluate the status of the cerebral circulation required in patients presenting with significant risk factors for cervical artery dissection. In such cases, approach the treatment with caution until a specific determination is made.
APPENDIX C. PERTINENT CLINICAL INFORMATION

(1) Thoracic spine trauma

The thoracolumbar injury severity scale (TLISS) may be helpful in referral decision-making process. The scale is based on the mechanism of injury, the integrity of the posterior ligamentous complex, and the neurologic status.iii The TLISS has good reliability and compares favorably to other contemporary thoracolumbar fracture classification systems.iv

</tbody>
</table>

The score is a total of 3 components: injury mechanism, PLC integrity, and neurologic status. A score of ≤3 suggests nonoperative treatment (bracing); 4, operative or nonoperative treatment; and ≥5 suggests operative treatment.

(2) Cervical spine trauma

Risk factors for WAD may include personal, societal, and environmental factors. Both physical and psychological factors are likely to play a role in recovery or non-recovery from whiplash injury. High initial symptom severity (high initial pain level, pain-related limitations, greater number of symptoms and painful body parts), greater psychological distress and passive coping may predict poorer outcome.v Finally, an important association exists between a Hx of a whiplash associated disorder, pain intensity, and disability and comorbidity (headache, LBP, digestive, and cardiovascular disorders).vi,vii

a. Adult Patient with Acute Neck Injury and Positive CCSR

Proposed whiplash associated disorders classification included Foreman and Croft (1995), the Quebec Task Forceviii and revised classification on Whiplash Associated Disorders.vi

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

A biopsychosocial model may improve WAD treatment and help prevent chronic disability.xi

Classification of patients with chronic WAD may include measures of self-efficacy, disability, and coping such as the NDI, Multidimensional Pain Inventory-Swedish version (MPI-S), The Self-Efficacy Scale, and the Coping Strategies Questionnaire.xii

b. Cervical Spine Injury Severity Score

The Cervical Spine Injury Severity Score (CSISS), which was developed to measure stability after cervical spine trauma, has excellent intraobserver agreement (ICC, 0.97-0.99) and interobserver agreement (ICC, 0.75-0.98). This classification system is based on morphological descriptions and on quantifiable values of stability and applies to all fractures of the
subaxial spine from the caudal aspect of C2 to T1. The score is based on bony and ligamentous disruption of the 4 columns of the cervical spine (anterior, right pillar, left pillar, and posterior osseous ligamentous complex) and correlates to increasing instability. Each column is graded using an analog scale from 0 to 5. Thus, the injury severity score ranges from 0 to 20, with 0 being no injury and 20 the most severe. The CSIIS does not take into account neurologic function or deficits. A morphologic description of subaxial cervical fracture is proposed.  

For more information on nonoperative management and treatment of spinal injuries and timing of surgical intervention in spinal cord injuries, see the reviews from Rechtine and Felings.

(3) Clinical Criteria for the Diagnosis of LDH

Nerve root pain due to disc-root conflict should be deemed to be a symptom of multifactorial origin in which the neural and perineural inflammatory reactions and their mediators play a major role that is flanked by venous stasis due to mass effect on the perineural circulation. Nerve compression appears to play an adjuvant role by generating nerve conduction abnormalities due to fiber demyelination by a direct or indirect anoxic-ischemic mechanism.

Clinical criteria for the diagnosis of LDH include sciatic pain that originates at the back or buttock and radiates below the knee, either unilaterally or bilaterally, typically involving the foot. Often, a history of recurrent LBP over several months or years, with occupational risk factors, is reported before leg pain onset. The patient often has difficulty rising from a sitting or supine position and typically experiences only partial pain relief while supine. Coughing or sneezing often exacerbates the low back and leg pain (positive Valasalva).

On physical examination, the patient is in acute distress and may manifest an antalgic posture/gait and decreased lumbar lordosis due to marked paraspinal muscle guarding. Lumbar spine ranges of motion may be restricted, especially in forward flexion. Lower extremity neurologic examination may reveal diminished deep tendon reflexes, loss of motor power, and sensory deficit of the involved nerve root (L4, L5, or S1). Reduced ankle reflex (L5-S1), weakness of ankle dorsiflexion (L4-5), foot drop, or weakness of the big toe (L5) requires special attention, as does reduced light touch in the L4, L5, or S1 dermatome. Straight leg raise will typically be restricted on the involved side with a high sensitivity (0.8) but a low specificity (0.4), whereas a crossed SLR (well leg-raise test) has a low sensitivity (0.35) but a high specificity (0.9) for the diagnosis of herniated discs. This may be confirmed by nerve root tension tests such as bowstring and Braggard’s.

Wasserman maneuver (Ely’s test) evokes pain by stimulating the L2-L4 nerve roots when hyperextending the hip with the knee flexed at 90 while the patient is prone. Examination may reveal reduced patellar reflex (L2-L4), weakness of the quadriceps (L2-4), and possibly of ankle dorsiflexion (L4-5), and/or reduced light touch in L2, L3, or L4 dermatome. Bony and soft tissue tenderness may be noted over the lumbar and gluteal region, although not a prominent feature.

(4) Thoracic Spine Osteoporosis

A woman 65 years of age with one vertebral fracture has a 1 in 4 chance of another fracture over 5 years, which can be reduced to 1 in 8 by treatment. Positive treatment decisions are often contingent on identifying a vertebral fracture.

Although it may not be possible to restore normal bone structure in women with osteoporosis, antiresorptive agents (eg, bisphosphonates, selective estrogen receptor modulators) can substantially reduce the risk of new vertebral fracture, even without corresponding increase in bone mass density, by reducing excessive bone turnover. Elevated bone turnover can be assessed with a number of biochemical markers such as osteocalcin, bone-specific alkaline phosphatase, C-telopeptides of type I collagen and N-telopeptide cross-links of type I collagen.

a. Important Osteoporosis Risk Factors:
   a. Age ≥50 (higher risk >70);
   b. BMI or weight (<19 kg/m² or <57 kg);
   c. Ethnic group or race (white or Asian);
   d. Menopause before age 45;
   e. Loss height (>4 cm);
   f. Hx of corticosteroid Tx for rheumatoid arthritis and other immune and inflammatory disorders (5-7.5 mg/d x 3 months);
   g. Hx of fragility fracture after age 45 of one of the following sites: hip, rib, wrist;
   h. No Hx of hormone replacement therapy/estrogen such as premarin, estrace, estraderm, estrab;
   i. Vitamin D and vitamin K deficiency, aluminum bone disease (dialysis, TNP), hypogonadism, malabsorption syndromes; Hx of anorexia/bulimia nervosa, female athlete triad
   j. Excessive alcohol/caffeine intake; smoking, dilantin;
k. Immobilization >4 weeks after age 45;
l. Low birth size and poor childhood growth
m. Elevated blood pressure;
n. Cognitive decline.

b. **Osteoporosis Risk Assessment**

In healthy perimenopausal and early postmenopausal women (45-64 years), consider using the Osteoporosis Self Assessment Tool (OST score): the OST considers only 2 variables: (weight in kilograms – age)/5. The cut-off for a positive test is <2, indicating this woman should be referred for DEXA.

In higher-risk patients, use either one of the following 3 clinical tools as they were all found to be highly sensitive:

1. Osteoporosis Risk Assessment Instrument (ORAI) which considers age, weight, and estrogen use (Table 1).
2. Simple Calculation of Osteoporosis by Estimation (SCORE) which considers 6 variables (race, RA, history of fracture, age, estrogen, weight (in pounds) (Table 2).
3. Age, years after menopause, age at menarche, BMI (AMMED) (Table 3).

**Table 1. Osteoporosis Risk Assessment Instrument (ORAI).**

(5) **Clinical Criteria for the Diagnosis of Cervicobrachial Syndrome**

Cervical radiculopathy is a disorder of the cervical spinal nerve root, and most commonly is caused by a CDH or other space-occupying lesion. The annual incidence of cervical spine disc herniation with radiculopathy is approximately 5.5 per 100,000 and tends to affect patients aged 35 to 55 years of age. The levels most commonly affected are C5-C6 and C6-C7. A clinical diagnosis of CDH is possible in only 50% to 75% of cases of cervical radiculopathy as a wide variation of presentations exists even with only 1 nerve root. Patients should be monitored as signs and symptoms may progress in the first 2 to 3 weeks.

Historical questions with diagnostic accuracy include shoulder/scapular pain, symptoms influenced by neck movement, presence of numbness/tingling, intermittent signs and symptoms, and symptoms that interrupt sleep.
On physical examination, the patient is generally in acute distress and may manifest an antalgic posture. The upper limb tension test (ULTT) appears useful as a screening test given its high sensitivity (0.97). If the ULTT is negative, then cervical radiculopathy (CR) can essentially be ruled out, and the need for further work up or treatment for CR is minimized. Findings with useful diagnostic accuracy include cervical spine ranges of motion restriction (ipsilateral rotation less than 60°, and neck flexion less than 55°). Although not very sensitive, the following tests have moderate to high specificity for CR: traction/neck distraction, spurling, Valsalva, and the shoulder abduction test, reduced or absent dermatomal sensation (C5 most accurate), motor power, and deep tendon reflex (biceps most accurate). The probability of the condition increases with several positive findings.

(6) Persistent Neck Pain

(a) Identification of psychological risk factors (yellow flags):
- Obvious psychological distress
- Severe pain beyond what is expected
- Hx of prior significant pain recurrences
- Higher than expected functional impairment
- Unexplained widespread pain
- Pain and limitation not consistent with objective findings.

(b) Mental status indicators of significant anxiety or depression:
- Insomnia or nightmares
- Irritability
- Withdrawal
- Panic episodes or anxiety during the day or night
- Persistent tearfulness
- Poor concentration
- Inability to enjoy
- Poor appetite/weight loss
- Poor libido
- Thoughts that “life is not worth living”

Clinicians are encouraged to use validated patient self-administered questionnaires to evaluate perceived neck pain, function, disability, and psychosocial status.

(c) Suspected cervical artery dissection (VAD, CAD), TIA (vertebrobasilar ischemia, carotid artery ischemia), stroke.

Acute neck pain is generally due to musculoskeletal conditions that respond well to conservative therapy. Risks of adverse events need to be addressed when considering any form of therapy. Several risk factors have been proposed for cervical artery dissection. Cervical artery dissection may be considered multifactorial, resulting from cumulative events over a period of time. Patient having cervical artery dissections tend to be females under the age of 45: recently, an etiologic model to help explain the pathogenesis of cervical artery dissection has been proposed. Recent studies and reviews discussing the nature of the association between vertebrobasilar stroke and chiropractic care are available elsewhere.

It is likely that patients in the early stages of VBA stroke are presenting to a health care professional because of neck pain and headache due to pre-existing vertebral artery dissection which is a risk factor for VBA stroke.

None of the proposed risk factors may be visualized on conventional radiography. Few case reports have linked advanced cervical spondylolisthesis to vertebral artery dissection, suggesting ostophytes off the uncovertebral joint or superior articular process may be associated to a dissection. Advanced cervical spondylolisthosis mostly concerns the older age population which would normally undergo radiographs when presenting with a neck complaint. Major neck trauma is likely an independent risk factor for CAD. Again, imaging studies are indicated in those circumstances.

APPENDIX F. ADDITIONAL READING RECOMMENDED ON SPINAL MRI

APPENDIX G. ACKNOWLEDGMENTS

The authors express their sincere appreciation to all Delphi panelists (phase 5), external reviewers (phases 4 and 7), and to the quality of literature assessors (phase 2): Jeffrey Cooley, Jonathon Egan, Michael Morgan, Julie O'Shaughnessy, and Jason Napuli, whose significant contributions were essential in the completion of this project. We are grateful to chiropractic college presidents for recommending faculty members for the Delphi panel. We have appreciated the feedback received by colleagues in the field during and after the worldwide consultation on the Web (Phase 6). Many thanks to Dr Andre Cardin of Université du Québec à Trois-Rivières for his significant input in the initial draft (phase 3); Dr Michelle Wessely of the Institut Franco-Européen de Chiropratique and Dr Julie-Marthe Grenier of Université du Québec à Trois-Rivières for their valuable editorial input; and to Drs Carlo Ammendolia, DC, PhD; Joe Lemire DC, MSc; John Triano, DC, PhD; and Jacques Duranceau, MD, for providing constructive advice. The authors are indebted to those who assisted us during all or part of the project, including Drs Mark Laudadio, DC; Christian Eid, DC; Julie Roy, DC; Nicholas Beaudoin; and Mme Valérie Lambert, academic and technology support, Computer System Development Division at UQTR. Finally, we would like to thank Mrs Vicki Pennick, RN, BScN, MHSc, Senior Clinical Research Project Manager, Managing Editor, Cochrane Back Review Group, Institute for Work and Health for her valuable advice and pertinent comments and suggestions as a public representative. We further apologize, once again, to those who experienced temporary technical difficulties with the evaluation questionnaires at the onset of Website consultations (Delphi, Public and External review).

We wish to acknowledge all Delphi panelists who have dedicated their time to this project. The following is a list of Delphi panelists who have agreed to be acknowledged for their significant contribution to the research project.

Allan Adams, DC, MSEd
Texas, USA, Texas Chiropractic College (Academic and Researcher)

Peter Aker, DC, MSc, FCCS, FCCR
Ontario, CANADA (Clinician and Researcher)

Thomas F. Bergmann, DC
Minnesota, USA, Professor, Northwestern Health Sciences University (Academic, Clinician)

Douglas G. Brandvold, DC
British Columbia, CANADA (Clinician)

Gert Bronfort, DC, PhD
Minnesota, USA, Professor, Northwestern Health Sciences University (Researcher and Academic)

Peter Bull, DC, MAAppSc, FICC
Sydney, AUSTRALIA, Senior Lecturer, Director of Postgraduate Studies, Macquarie University (Academic and Clinician)

Jeanmarie Burke, PhD
New York, USA, Research Director, New York Chiropractic College (Researcher and Academic)

Jane Cook, DC, DACBR
Bournemouth, UK, Anglo European Chiropractic College (Academic)

Jeffrey Cooley, DC, DACBR
Perth, West Australia, Senior Lecturer, Murdoch University (Academic)

Martin Descarreux, DC, PhD
Quebec, Canada, Université du Québec à Trois-Rivières (Researcher, Academic and Clinician)

Renee DeVries, DC, DACBR
Minnesota, USA, Associate Professor and Consulting Radiologist, Northwestern Health Sciences University (Academic)

Paul Dougherty, DC, FACO
New York, USA, New York Chiropractic College (Academic)

Dennis Enix, DC, MBAc
Missouri, USA, Associate Professor of Research, Logan College of Chiropractic (Researcher and Clinician)

Ronald C. Evans, DC, FACO, FICC
Iowa, USA, Senior Orthopedist, Senior Trustee, Foundation for Chiropractic Education and Research, Senior Member, Chiropractic Healthcare Benefits Advisory Committee, Health Affairs, Department of Defense (Researcher and Clinician)

Roni Evans, DC, MSc
Minnesota, USA, Dean of Research, North Western Health Sciences University (Researcher)

Francis Fontaine, DC, MD
Quebec, Canada, Lecturer, Université du Québec à Trois-Rivières (Clinician)

Simon Forster, DC, DABCO
Texas, USA (Clinician)

Bryan Gatterman, DC, DACBR
California, USA, Life West Chiropractic College (Academic and Clinician)
Claude Gauthier, DC
Quebec, Canada (Clinician)

Kristin L. Grace, DC, DACBR
Pontypridd, Wales, University of Glamorgan, School of Applied Sciences (Academic and Clinician)

Gary Greenstein, DC
Connecticut, USA (Clinician)

Julie-Marthe Grenier, DC, DACBR
Quebec, Canada, Université du Québec à Trois-Rivières (Academic and Researcher)

Mitchell Haas, DC, MA
Oregon, USA, Dean of Research, Western States Chiropractic College (Academic and Researcher)

François Hains, DC, MSc, FCCS
Quebec, Canada (Clinician)

Michael W. Hall, DC, DABCN
Texas, USA, Associate Professor, Parker College of Chiropractic (Academic and Clinician)

Jan Hartvigsen, DC, PhD
Odense, Denmark, Dean of Research, University of Southern Denmark (Academic and Researcher)

Shawn Henderson, DC, FCCRS(C), FCCO(C)
Ontario, Canada (Clinician)

William Hsu, DC, DACBR
Ontario, Canada, Associate Professor, Canadian Memorial Chiropractic College (Academic)

Eric Jackson, DC, FCCRS
Ontario, Canada (Clinician)

Amanda Kimpton, BAppSc(Chiro), PhD
Victoria, Australia, RMIT University (Academic and Clinician)

Dana J. Lawrence, DC, FICC
Iowa, USA, Associate Professor, Palmer Chiropractic College (Academic and Researcher)

Douglas Lawson, BA, DC
Alberta, Canada (Researcher and Clinician)

Kathleen Linaker, DC, DACBR
Georgia, USA, Assistant Professor, Director Clinic Radiology, Life University College of Chiropractic (Academic, Clinician)

Tracey Littrell, DC, DACBR
Iowa, USA, Associate Professor, Diagnosis and Radiology, Palmer-Davenport Chiropractic College (Academic)

Stephan Mayer, Bsc, DC
California, USA, Chair of Diagnostic Sciences and Associate Academic Dean, Cleveland Chiropractic College (Academic)

Peter W. McCarthy, BSc (Hons), PhD
Wales, UK, University of Glamorgan (Researcher and Academic)

Ian D. McLean, DC, DACBR
Iowa, USA, Professor, Clinical Radiologist Professor, Director of Clinical Radiology and Chiropractic Residencies, Palmer-Davenport Chiropractic College (Academic and Clinician)

Michael Mestan, DC, DACBR
New York, USA, Head of Department of Chiropractic Clinical Sciences, New York Chiropractic College (Academic)

Timothy J. Mick, DC, DACBR, FICC
Minnesota, USA (Clinician)

Silvano Mior, DC, FCCS
Ontario, Canada, Canadian Memorial Chiropractic College (Academic, Researcher and Clinician)

Tom Molyneux, DipAppsc (H Biology), DipAppSc(Chiro), BAppSc(Chiro), DACBR, FACCR, GradDipTertEd.
Victoria, Australia, RMIT University (Academic)

William E. Morgan, DC
Maryland, USA, Adjunct professor, New York College of Chiropractic, National University of Health Sciences (Clinician)

Eli Morton, DC
British Columbia, Canada (Clinician)

Greg Norton, DC, FACO, FIACN
Iowa, USA (Clinician)

Sandra O’Connor, DC, DACBR, FCCR
Ontario, Canada (Clinician)

Rosemary Pace, RN, DipAppSc(MedRad), MEd (ICT), MBus, GradDipEd, GradDipBus
Victoria, Australia, RMIT University (Academic and Researcher)
Joseph Pfeifer, DC
New York, USA, New York Chiropractic College (Academic)

John Pikula, DC, FCCR(C), FCCS(C), FCCO(C)
Ontario, Canada (Clinician)

Brock Potter, DC
British Columbia, Canada (Clinician)

Tania C. Pringle, BPE, BA, DC, DACBR, FCCR(C)
Ontario, Canada, Assistant Professor, Canadian Memorial Chiropractic College (Academic)

Serge Roux, DC, DABCO
Quebec, Canada (Clinician)

Peter Scordilis, DC
New Jersey, USA (Clinician)

Thomas A. Souza, DC, DACBSP
California, USA, Dean of Academic Affairs, Palmer Chiropractic College West (Academic and Clinician)

John Stites, DC, DACBR
Iowa, USA, Palmer Chiropractic College (Academic)

Rand Swenson, DC, MD, PhD
New Hampshire, USA, Associate Professor of Anatomy and of Medicine, Chairman, Department of Anatomy, Dartmouth Medical School (Academic, Clinician)

John Sweaney, AM, DC
New South Wales, Australia, Chiropractic Education Consultant (Clinician)

Cliff Tao, DC, DACBR
California, USA (Clinician)

Jeffrey Thompson, DC, DACBR
Texas, USA (Clinician and Researcher)

Michelle A. Wessely, BSc, DC, DACBR
Paris, FRANCE, Professor, Head of Radiology and Clinical Research, Institut Franco-Europeen de Chiropratique (Academic and Clinician)

Michael Whitehead, BS, DC, DACBR
Missouri, USA, Chair of Diagnostic Sciences, Cleveland Chiropractic College (Academic and Clinician)

Kenneth J. Young, DC, DACBR, FCC(UK)
Wales, UK, Senior lecturer in radiology, University of Glamorgan (Academic and Clinician)

DELPHI PROCESS ADVISORS
Meridel I. Gatterman, MA, DC, MEd,
Colorado, USA, Chiropractic Educational Consultant

Peter Miller, BSc, MSc, FCC (Orth)
Bournemouth, UK, Anglo-European College of Chiropractic
